Park-Davis Pharmaceutical Research

Cefdinir capsules (300 mg) and suspension (125 mg/5 mL)

REMARKS/COMMENTS:

This application provides a proposal for the marketing of a semisynthetic cephalosporin, Cefdinir, for the treatment of patients with community acquired pneumonia, acute exacerbations of chronic bronchitis, acute otitis media, acute maxillary sinusitis, pharyngitis/tonsillitis, and uncomplicated skin and skin structure infections.

CONCLUSIONS & RECOMMENDATIONS:

The application is approvable from the microbiological viewpoint under section 507(b) of the Act when changes are made to the MICROBIOLOGY section of the package insert. The changes needed should be sent to the sponsor. These revisions are listed as notification to the sponsor at the end of this review on pages 127 to 134.

I INTRODUCTION

Cefdinir is a new, orally administered member of the cephalosporin class of β -lactam antimicrobial agents. It has been evaluated in clinical trials in adults and children against community-acquired infections of the upper and lower respiratory tracts and infections of the skin and skin structures. Due to its spectrum of antimicrobial activity and pattern of β -lactamase resistance, cefdinir was targeted against the following species of bacteria: *Staphylococcus aureus*, *Streptococcus agalactiae*, *S. pneumoniae*, *S. pyogenes*, *Escherichia coli*, *Haemophilus influenzae*, *H. parainfluenzae*, *Klebsiella pneumoniae*, and *Moraxella catarrhalis*.

Based on pilot plasma concentration studies performed in humans, the recommended cefdinir regimen for the treatment of infections in adults, using a capsule formulation, is either 300 mg twice a day or 600 mg once daily. The equivalent oral doses of suspension in children, ranging in age from 6 months to 12 years, are 7 mg/kg twice a day or 14 mg/kg once daily.

II PRECLINICAL EFFICACY (*IN VITRO*)

A Mechanism of Action

Cephalosporins exert their antibacterial activity by inhibiting bacterial cell wall synthesis. β -lactams bind to proteins on the inner surface of the bacterial cell membrane. These proteins, penicillin binding proteins (PBPs), are of 3 classes: transpeptidases; carboxypeptidases; and endopeptidases. These enzymes are responsible for the final assembly of newly synthesized cell wall, external to the cell membrane.

Cephalosporins inhibit the transpeptidase enzyme responsible for cross-linking nascent peptidoglycan. The cephalosporin β -lactam ring sterically mimics the D-ala-D-ala amino acid sequence of the pentapeptide precursor, covalently binding at the transpeptidase active site, rendering the enzyme and the cephalosporin inactive. Cephalosporins are bactericidal by virtue of cell wall synthesis inhibition, although the actual killing mechanism is unclear.

In a study by Yasuhiro Mine et al.⁽¹⁾ relative PBPs affinities of cefdinir in *S. aureus* 209P JC-1, *E. faecalis* FP183, and *E. coli* NIHJ JC-2 were investigated. The data are presented in Table 1. Affinities of cefdinir for PBPs 1, 2, and 3 (classified by molecular weight) of *S. aureus* and PBPs 1a, 1b, 2, 3, and 4 of *E. coli* were generally equal to or greater than those of cefixime, cefaclor, or cephalexin. Cefdinir and the 3 reference drugs had poor affinity for PBP 4 of *S. aureus* and PBPs 5 and 6 of *E. coli*. Against *E. faecalis* PBPs, cefdinir showed very high affinity for PBP 2 and 3, moderate affinity for PBP 1, and low affinity for PBPs 5 and 4, while cefaclor showed very high affinity for PBPs 2 and 1, moderate affinity for PBP 3, and low affinity for PBPs 4 and 5.

TABLE 1. Affinity of Cefdinir and Reference Antibiotics for Penicillin-Binding Proteins (PBPs)

	PBPs	IC ₅₀ ^a			
		Cefdinir	Cefixime	Cefaclor	Cephalexin
<i>Staphylococcus aureus</i> 209P JC-1	1	0.58	2.9	0.2	0.2
	2	0.17	<0.2	125	1.7

	6	>125	13	>25	>125
	MIC (μ g/mL)	0.2	0.2	3.13	12.5

^a Inhibitory concentrations (μ g/mL) of drug required to reduce [¹⁴C]benzylpenicillin binding by 50%

Takeshi Yokota et al.⁽²⁾ supported part of the above information by reporting that cefdinir manifested higher binding affinities to PBPs 2 and 3 of *S. aureus* 209P, PBP 1bs, 2, 3, and 4 of *E. coli* NIHJ JC-2, and all fractions except PBP 2B of *S. pneumoniae* 13 than cefaclor. Kazuo Hatano et al.⁽⁴⁾ also demonstrated that cefdinir's high binding affinities for PBPs, 2, and 3 of *S. aureus* and PBPs 1 and 2 of *S. pyogenes* were the reason for drastic morphological changes and antibacterial activity.

Consistent with this mechanism of action, cefdinir induced filamentation in *E. coli* at concentrations as low as 0.025 μ g/mL and produced lysis at 0.78 μ g/mL.⁽³⁾ Exposure of *E. faecalis* to 6.25 μ g/mL of cefdinir for 2 hours produced nonseparating cells with a multiple thick

cross wall and 10% lysis.⁽⁵⁾ In *S. aureus* exposed to cefdinir at concentrations as low as 0.05 μ g/mL, the cross walls were swollen, the next cross wall synthesis started before completion of septation, and lysis was triggered at the site of cross wall formation resulting in cell skeletons in most cells. In *S. pyogenes*, 0.012 μ g/mL of cefdinir induced swollen and incomplete cross walls, as well as lysis in a large cell population; and at 0.048 μ g/mL, there was almost complete inhibition of cross wall formation and lysed cells.⁽⁶⁾

B. Antimicrobial Spectrum of Activity

Cefdinir has been tested for *in vitro* activity against a variety of microorganisms derived from infections throughout the world. The data derived from these studies are summarized in Table 2. These studies were conducted using standardized and controlled *in vitro* susceptibility test methods. Minimum inhibitory concentrations (MICs) were determined by a dilution method, most commonly using Mueller-Hinton (MH) broth for aerobes, supplemented as required for support of fastidious organisms and Wilkins-Chalgren (WC) agar for anaerobes. For investigators using broth microdilution methods an inoculum of about 10⁵ CFU per milliliter was used in most studies. For investigators using agar dilution an inoculum of about 10⁴ CFU per spot for aerobes and 10³ CFU per spot for anaerobes was used in most studies. Tests for aerobes were read after overnight incubation at 35-37°C, but some anaerobes required up to 48 hours incubation. These agar and inocula are those recommended by the National Committee for Clinical Laboratory Standards (NCCLS).

The sponsor proposed susceptibility criteria based on human pharmacokinetics data⁽⁶⁾ and the 600-mg once or 300-mg twice daily dose of cefdinir used in clinical evaluations, as follows: Susceptible, MIC \leq 1.0 μ g/mL; Intermediate, MIC = 2 μ g/mL; and Resistant, MIC \geq 4 μ g/mL.

Using these criteria, most species of gram-positive isolates are susceptible (median MIC₅₀s \leq 1.0 μ g/mL) to cefdinir. This includes the following species: *Gardnerella vaginalis*; *Gemella morbillorum*; methicillin/oxacillin-susceptible isolates of *Staphylococcus aureus*, *S. epidermidis*, *S. haemolyticus*, *S. saprophyticus*, *S. xylosus*, and coagulase-negative Staphylococci; *S. capitis*; *S. cohnii*; *S. hominis*, *S. simulans*; *Streptococcus anginosus*; *S. bovis*; *S. constellatus*; *S. equinus*; *S. pyogenes*; *S. agalactiae*; *S. intermedius*; *S. mitis*; penicillin-susceptible *S. pneumoniae*; *S. salivarius*; and *S. sanguis*.

In addition, the following fastidious gram-negative bacteria are susceptible to cefdinir: *Haemophilus influenzae* and *H. parainfluenzae*; *Moraxella catarrhalis*, *Neisseria gonorrhoeae*, and *N. meningitidis*. Cefdinir's activity extends to *Aeromonas hydrophila* and the following enteric species: *Citrobacter diversus*; *Pantoea (Enterobacter) agglomerans* and *E. sakazakii*; *Escherichia coli*; *Klebsiella oxytoca* and *K. pneumoniae*; *Proteus mirabilis*; *Salmonella enteritidis* and *S. typhi*; and *Yersinia enterocolitica*.

Park-Davis Pharmaceutical Research

Cefdinir capsules (300 mg) and suspension (125 mg/5 mL)

Susceptible strictly anaerobic species are *Clostridium perfringens*; *Peptostreptococcus anaerobius*, *P. asaccharolyticus*, *P. magnus*, *P. micros*, and *P. prevotii*; *Porphyromonas gingivalis*; *Prevotella intermedia* and *P. oralis*, and *Propionibacterium acnes*.

According to the sponsor since spectrum of activity of cefdinir includes bacterial strains that produce a wide variety of β -lactamases, cefdinir has been evaluated in clinical trials as an oral cephalosporin for the treatment of the following community-acquired infections:

Lower Respiratory Tract Infections:

- Community-acquired pneumonia caused by susceptible strains of *Haemophilus influenzae*, *Haemophilus parainfluenzae*, *Streptococcus pneumoniae*, *Staphylococcus aureus*, *Moraxella catarrhalis*, *Escherichia coli*, and *Klebsiella pneumoniae*.
- Acute exacerbations of chronic bronchitis caused by susceptible strains of *Haemophilus influenzae*, *Haemophilus parainfluenzae*, *Streptococcus pneumoniae*, *Staphylococcus aureus*, *Moraxella catarrhalis*, *Escherichia coli*, and *Klebsiella pneumoniae*.

Upper Respiratory Tract Infections:

- Acute maxillary sinusitis caused by susceptible strains of *Haemophilus influenzae*, *Haemophilus parainfluenzae*, *Streptococcus pneumoniae*, *S. pyogenes*, *Staphylococcus aureus*, *Moraxella catarrhalis*, *Escherichia coli*, and *Klebsiella pneumoniae*.
- Pharyngitis/tonsillitis caused by susceptible strains of *Streptococcus pyogenes*.

Uncomplicated skin and skin structure infections caused by susceptible strains of *Staphylococcus aureus*, *Streptococcus pyogenes*, *Streptococcus agalactiae*, and *Klebsiella pneumoniae*.

An analysis of the activity of cefdinir against the most frequently encountered pathogens is given in Table 3. Included for reference are other oral cephalosporins with similar antibacterial properties and the most commonly used oral penicillin (amoxicillin). The data show that cefdinir has good antibacterial activity against most of the bacterial strains isolated from the infections.

NDA 50-739 and 50-749

Park-Davis Pharmaceutical Research

Cefdinir capsules (300 mg) and suspension (125 mg/5 mL)

described above, i.e., methicillin/oxacillin-susceptible *Staphylococcus aureus*, *Streptococcus pyogenes*; penicillin-susceptible *Streptococcus pneumoniae*; *Haemophilus influenzae*; *Moraxella catarrhalis*, *Escherichia coli*; and *Klebsiella pneumoniae*. Cefdinir is almost 10-fold more active against methicillin/oxacillin-susceptible *Staphylococcus aureus* than cefpodoxime, the compound with the most similar spectrum. Cefdinir is also almost 10-fold more active against methicillin/oxacillin-susceptible *Staphylococcus aureus*, *Streptococcus pyogenes*; penicillin-susceptible *Streptococcus pneumoniae*; *Haemophilus influenzae*; *Moraxella catarrhalis*; *Escherichia coli*; and *Klebsiella pneumoniae* than the comparator cefaclor.

Cefdinir is not effective against all the Enterococci, methicillin/oxacillin-resistant staphylococci, penicillin-resistant pneumococci, all the *Acinetobacter* species, *Burkholderia cepacia*, all *legionella* species, all the pseudomonads, *Stenotrophomonas maltophilia*, all *Citrobacter* species, *Enterobacter aerogenes*, *E. Cloacae*, *Morganella morganii*, *Proteus vulgaris*, all *Providencia* species, and all *Serratia* species.

The NDA holders letter of January 1993 suggested that at least 100 isolates from each species should be tested. Therefore, only species with around 100 isolates will be considered for inclusion in the *in vitro* section (second list) of the package insert. The NDA holders letter also states that in order to be included in the label (second list) a microorganism should be a significant (not anecdotal) pathogen at the body site(s) or in the infection(s) for which clinical effectiveness for other pathogens has been established. Since the sponsor is requesting community-acquired pneumonia, acute exacerbations of chronic bronchitis,

acute maxillary sinusitis, pharyngitis/tonsillitis, and uncomplicated skin and skin structure infections, only potential pathogenic microorganisms usually found at these sites will be included in the second list of the label.

In a study by Neil, HC, et al., cellulitis was tested for MTC variance on different media (Mueller-Hilton broth vs agar, Mueller-Hilton, brain-heart infusion, and nutrient agar), across a pH range of 6 to 7.5. MTCs were within a 2-fold range for all tests versus 5 strains each of *S. aureus*, *E. coli*, *K. pneumoniae*, *E. cloacae*, and *C. freundii*. Serum and urine did not alter the MTCs or MBGs for *S. aureus*, *E. coli*, or *K. pneumoniae* (five isolates of each).

Several investigators studied the effects of culture medium, pH, horse and human serum, zinc, sheep red blood cells, 5% CO₂, and Mg⁺⁺ on *in vitro* results obtained with calf skin.

Effect of Medium, pH, Horse and Human Serum, Urine, Sheep Red Blood Cells, 5% CO₂ Atmosphere, and Mg²⁺ on Antibacterial Activity

Chloride tablets (300 mg) and suspension (125 mg/mL)

PARK-LAWNS FARMINGDALE RESORT

In a study by Nishino, T., et al., no effects were demonstrated when cefdinir was tested in heart murmur strains *S. aureus* 209-P JC, 1.56 to 3.13 for *E. coli* KC-14, 0.2 for *K. pneumoniae* KC-1, 0.39 to 0.78 for *P. vulgaris* OX-19, and 1.56 to 3.13 for *S.* marcescens T-55. In another series of experiments, the prevalence of 50% human serum had little effect on the activity of cefdinir against 25 clinical isolates consisting of 5 strains each of *S.*

Bacterial responses to cefdinir were unaffected by variations in pH. In a study by Fermandez-Roblas, R. Et al, changing the pH from 7.4 to 8.5 had no effect on the activity of cefdinir versus 10 strains of *P. mirabilis* and *K. pneumoniae* in either DST or MHA. (The MIC₉₀ values and ranges obtained at pH 8.5 were virtually identical to those indicated above). When compared in MHA, similar MICs were found for cefdinir at pH 5.4, 6.4, 7.4, and 8.4 (Mlide, Y., et al). MIC ranges (in µg/mL) were 0.025 to 0.05 for *K. pneumoniae* NCTC 418. In a study by Marache, A. Et al, utilizing 14 stephylcoccal isolates, no major MIC shifts occurred when the pH of Mueller-Hinton broth was varied between 5.5, 7.0, or 8.0. However, discopant results were reported in another study by Nishimo, T. Et al. When tested in heart infusion agar at pH 5.5, the MIC for *K. pneumoniae* T-55 was 6.25 µg/mL, contrasted with MICs of 0.78 and 0.39 µg/mL at pH 7.0 and 8.5. The MIC ranges (in µg/mL) for *K. aerogenes* 209-P JC, E. coli JC-1, K. pneumoniae KC-1, and *P. mirabilis* ranged as follows: 0.025 to 0.2, 0.2 to 0.39, 0.1 to 0.39, and 0.39 to 0.78.

In a study by Fernández-Robles, R. Et al., variations in culture medium had no effect on cellulase MHA versus MHA) in Diagnostic Sensitivity Test Agar (DST) and MHA at pH 7.4. Respective AUC₁₀₀ values and ranges for cellulase were 0.12 µg/ml and 0.06 to 0.12 µg/ml. For P. mirabilis in both media similarly idealized in both media were the MUC₁₀₀ and ranges for K. pneumoniae which were 0.5 µg/ml and 0.06 to 0.5 µg/ml, respectively. Another study by Nishino, T. Et al., compared heat inactivation agar, nutrient agar, trypticase soy agar, and MHA with a similar outcome. MUC ranges (in µg/ml) for S. aureus 209P-JC, E. coli KC-14, K. pneumoniae KC-1, P. vulgaris OX-19, and S. marcescens T-55 were as follows: 0.05 to 0.2, 0.1 to 0.2, 0.05 to 0.2, 0.2 to 0.39, and 1.56 to 1.56, respectively.

A second study by Yilinc, Y., et al., noted a 2- to 8-fold increase in MLCs for E. faecalis due to medium effects (based on results obtained with sensitivity test agar versus heart infusion agar).

Cefdinir tablets (300 mg) and suspension (125 mg/5 mL)

In summary, modifications in susceptibility test conditions are generally not expected to have any significant effects on *in vitro* results obtained with cefdinir. These include culture medium, pH, and dilution factors.

	S. aureus (2)				
	0.5	0.5	0.25	0.25	0.5

	(SBG), 5% CO ₂ , Atmosphere, and High Mg ⁺⁺				

TABLE 9. Cefdinir Activity in 5% Sheep Red Blood Cells

The following parameters had no significant effect on the antibacterial activity of cefdinir on MHA. 5% sheep red blood cells, 5% CO₂, and a Mg⁺⁺ content tenfold greater than that found in normal agar (Bugges, B.M., et al.). These results are shown in Table 9.

Buschelman, B.J., et al., demonstrated that the incorporation of 5% sheep blood in MHA produced a significant enhancement of the activity of cefdinir against *Enterococcus faecalis*. The mean zone diameter produced by 5- μg cefdinir disks against *E. faecalis* isolates was 13.6 mm on MHA containing 5% sheep blood, but was 9.2 mm on unsupplemented MHA; only 2 isolates showed no increased zone diameter. Agar dilution MICs against 10 isolates were 0.5 to 2 $\mu\text{g}/\text{mL}$ in MHA with 5% sheep blood (median 1 $\mu\text{g}/\text{mL}$), whereas all 10 had MICs of 2 $\mu\text{g}/\text{mL}$ in MHA. 5% sheep red blood cells, 5% CO₂, and a Mg⁺⁺ content tenfold greater than that found in normal agar (Bugges, B.M., et al.). These results are shown in Table 9.

Staphylococcal isolates was tested in 50% human serum or human urine, MIC values generally ranged by 2-fold (Marchese, A. et al.). 2-fold increased MIC (Garrett-Rodriguez, J.A., et al.). When the susceptibility of 14 *cavariae*, *S. pneumoniae*, *S. pyogenes*, *H. influenzae*, and *M. catarrhalis*, producing at most a 2-fold increased MIC (Garrett-Rodriguez, J.A., et al.). When the susceptibility of 14

Cefdinir tablets (300 mg) and suspension (125 mg/5 mL)

In a study by Bugges, B.M. et al., the production of β -lactamase did not influence the degree of bactericidal action of cefdinir against *E. coli*, *K. oxytoca*, and *K. pneumoniae* (Table 11).

Cefadzilur was generally bactericidal against *S. pneumoniae*, *S. aureus*, *S. epidermidis*, *S. hominis*, *S. xylosus*, *S. haemolyticus*, *S. saprophyticus*, *S. capitis*, *H. influenzae*, *M. catarrhalis*, and *E. coli* (Table 10) and bacteriostatic against *P. mirabilis*, *E. cloacae*, and *C. freundii*. Cefadzilur was bactericidal against *S. aureus* in 3 of 4 studies and bacteriostatic against *K. pneumoniae* in 1 of 2 studies. These discrepancies may represent either a methodological variation or a strain dependency.

In a study by Minge, Y., et al. the mean MIC and MBC of cefadimur against *S. aureus* 2558 were 0.39 (range = 0.1-1.56) and 17.7 (range = 12.5-25) $\mu\text{g}/\text{mL}$ and against *E. coli* 3147 the mean MIC and MBC were 0.33 (range = 0.2-0.78) and 0.66 (range = 0.2-3.13) $\mu\text{g}/\text{mL}$ respectively. The bactericidal concentrations were 4x MIC for *S. aureus* and 1x MIC for *E. coli*. A greater than 3 log decrease in CFU/mL (colony forming units) was seen (Figures 1 and 2) between 6 and 24 hours for *S. aureus* 2558 and *E. coli* 3147. No regrowth was seen up to 24 hours of incubation. In other studies, similar kill curves have been obtained with *C. pneumoniae*, *S. aureus*, *H. influenzae*, *M. catarrhalis*, *E. coli*, and *S. pyogenes* (see references 4, 47, 63, 69, 74, and 76 listed on pages 2-26 in volume 47 of the submitted NDA 50-739).

The bactericidal activity of cefdinir has been demonstrated by several investigations.

D. Bactericidal Activity

horses and man serum, urine, sheep red blood cells, 2% CO_2 and Mg. However, the mucusion of 5% sheep blood in Mueller-Hilton Agar (MHA) appeared to enhance the activity of cedarin against isolates of *Enterococcus faecalis*.

Park-Davis Paracetamol Suspension 125 mg/5 mL

Combination activities of cefdinir with other antibacterial drugs were assessed by standard checkerboard titration and time-kill curves in a study by Marchesi, A et al. A total of 18 strains of the following species were tested: *S. aureus*, *S. epidermidis*, *S. saprophyticus*, *S. haemolyticus*, *S. hominis*, and *S. xylosus*. Penicillin-resistant isolates were included. The other antibiotics were *S. hominis*, *Neutromycin*, *Tiamycin*, *Techoplatin*, *Vancomycin*, and *Clethromycin*.

TABLE 12. Cefdinir Postantibiotic Effect (PAB)

Cefdinir tablets (300 mg) and suspension (125 mg/5 mL)

Park-Davis Pharmaceutical Research

The study of Neal, H.C. et al. is summarized in Table 13; Cefdinir was stable to a number of isolated gram-negative β -lactamases including TEM-1 and -2 (the most common plasmid enzymes). Supporting data are contained in Tables 13 through 19.

B. fragilis. These enzymes have been detected in a variety of species including *S. aureus*, *H. influenzae*, *M. catarrhalis*, *N. gonorrhoeae*, *C. freundii*, *E. cloacae*, *E. coli*, *K. oxytoca*, *K. pneumoniae*, *M. morganii*, *P. mirabilis*, *P. vulgaris*, *S. marcescens*, *P. aeruginosa*, *P. cepacia*, *S. maltophilia*, and *M. luteus*.

Cefdinir has been shown to be stable to the hydrolytic activity of a variety of β -lactamases of plasmid or chromosomal origin including the following types (Richmond-Sypes in *Antimicrob Agents Chemother* 1978, 22: 100-104): ampicillins, cephalosporins (including cephazidimes, cephazidimes, and oximinocephalosporinases), and extended spectrum β -lactamases.

A major component of the lack of susceptibility of bacteria to cephalosporins is associated with the β -lactamases produced by these microorganisms. Cefdinir and other cephalosporins have been developed which are stable to attack by β -lactamase.

G. Enzyme Hydrolysis Rates

A similar outcome was evident when the interaction of cefdinir with the same antibiotics was evaluated employing the time-kilil system. Inhibition occurred in the majority of the 126 combinations tested. Synergy was observed more frequently with the time-kilil method in 25 of 18 strains studied. Synergy was also produced with cefdinir and tetracycline (8 of 18 strains studied). Synergy was more common with cefdinir and vancomycin (4) of 18 strains studied. Synergy was also produced with cefdinir and tetracycline (3) and 2 each by the remaining 3 antibiotics. Again, synergism was not found.

These *in vitro* data indicate that no deleterious effects on the antibacterial activity of cefdinir should be anticipated when it is used in conjunction with other antibiotics.

Unlike cefaclor, cefdinir is generally stable to several of the new extended-spectrum β -lactamases of the following classes: cefotaximases, ceftazidimases, and cephalosporinases (Table 19).

Cefdinir has a β -lactamase stability profile generally better than that of cefaclor and cefuroxime (Tables 14-19). When compared to cefaclor, cefdinir shows greater sensitivity to some gram-negative cephalosporinases (Table 18).

Cefdinir was more stable to penicillinas than cefaclor. Mine, Y, et al demonstrated that the stability of cefdinir to cephalosporinases was dependent on the type, being relatively stable to types Ia and Ib while less stable to types Ic and Id and a cefuroximase (Table 14). Tomatsu, K. And coworkers demonstrated that cefdinir showed sensitivity to hydrolysis by the oxyminocephalosporinases (Table 15).

and OXA-2, *S. maltopehilia* β -lactamase also hydrolyzed cefdinir as did *P. vulgaris* enzyme. TM-3 β -lactamase hydrolyzed cefdinir as did both PSB-2 and PC-1 β -lactamase from *S. aureus*. Cefdinir was also stable to hydrolysis by K1 (Richtmond-Slykes IV), and *Moraxella catarrhalis*. Cefdinir was also stable to hydrolysis by β -lactamases), *Enterobacter cloacae* chromosomal P99 (Richtmond-Slykes Ia), *Klebsiella oxytoca*

enhanced expression of β -lactamase production. Couplin's diminished uptake in specifically constructed form-declining mutants which have an inhibitor of these enzymes, as shown by Neu, H.C. et al (Table 20). However, Jacoby, G.A. and coworkers have revealed that the activity of Cefdinir and other cephalosporins can be decreased by found β -lactamases (see Section G, Enzyme Hydrolysis Rates). Cefdinir also functions as an Due to its chemical structure, Cefdinir is able to resist enzymatic hydrolysis by the most commonly PBP's by mutation.

β -lactam resistance are reduced uptake of the molecule, or alteration of the target (PBP's) by both gram-positive and gram-negative bacteria. Two less common types of β -lactam antibiotics is primarily due to the production of inactivating enzymes. Resistance to β -lactam antibiotics is primarily due to the production of inactivating enzymes PBP's by mutation.

I. Mechanisms of Resistance

H. Assessment of Resistance

Cefdinir tablets (300 mg) and suspension (125 mg/5 mL)

Park-Davis Pharmaceutical Research

In the study performed by Mline, Y., et al., in which an ampicillin-resistant plasmid was introduced

did creditum. The *E. coli* strain, although cephalaxin and cefaclor had higher initial and posttransfer MICs than $1\mu\text{g}/\text{mL}$ for the former, and 0.78 and 100 $\mu\text{g}/\text{mL}$ for the latter. The 3 agents were similar against *JC-1*, which increased from 0.05 to 0.78 $\mu\text{g}/\text{mL}$. For *E. coli* 3147, the MIC was elevated from a baseline of 0.2 $\mu\text{g}/\text{mL}$ to a 14-transfer value of 6.25 $\mu\text{g}/\text{mL}$. In contrast, *S. aureus* developed resistance more rapidly to cephalaxin and cefaclor: pre- and posttransfer values were 1.6 and 100 $\mu\text{g}/\text{mL}$ for the former, and 0.78 and 100 $\mu\text{g}/\text{mL}$ for the latter. After 14 transfers through increasing concentrations of creditum, the MIC against *S. aureus* 209P was increased from 0.05 to 0.78 $\mu\text{g}/\text{mL}$. For *E. coli* 3147, the MIC was elevated from a baseline of 0.2 $\mu\text{g}/\text{mL}$ to a 14-transfer value of 6.25 $\mu\text{g}/\text{mL}$. In contrast, *S. aureus* developed resistance more rapidly to cephalaxin and cefaclor: pre- and posttransfer values were 1.6 and 100 $\mu\text{g}/\text{mL}$ for the former, and 0.78 and 100 $\mu\text{g}/\text{mL}$ for the latter. As is characteristic of cephalosporins, creditum resistance development was slow and stepwise.

MIC was 6×10^9 to 2×10^9 . In general, the range of resistance frequencies was 2×10^9 down to 1×10^9 , and the range for 10 \times MIC, the development of resistant strains was rare with all creditum concentrations used. At incubated for 48 hours at 37°C to permit the growth of single mutant cells into visible colonies. and 10 \times MICs with very heavy bacterial inocula (10^9 to 10^{11} cells per mL). The plates were evaluated by seeding agar plates containing concentrations of creditum equivalent to 2 \times , 5 \times , *Staphylococcus*, *S. haemolyticus*, and *S. hominis*. The frequency of isolation of resistant clones was determined with several species of *Staphylococcus*: *S. aureus*, *S. epidermidis*, *S. xylosus*, *S. saprophyticus*, *S. haemolyticus*, and *S. hominis*. The rate of development of spontaneous mutants was determined, respectively. The rate of development of spontaneous resistance among susceptible populations and patterns of multi-step development of resistance have been reported by Marthec, A. and Mline, Y. and their coworkers, respectively. Data regarding the frequency of resistant mutants among susceptible populations and patterns of multi-step development of resistance among susceptible populations and patterns of

β -lactamases, 100 μM nitrocefin was used as the substrate.

Creditum tablets (300 mg) and suspension (125 mg/ mL)

Park-Davis Pharmaceutical Research

NDA 50-739 and 50-749

Several reports have documented the activity of cefdinir against β -lactamase-producing bacteria which are frequently found in community-acquired infections: *H. influenzae*, *N. gonorrhoeae*, and *S. aureus*.^(17,24) The data are summarized in Table 22. In these species, cefdinir susceptibility was not diminished by the production of β -lactamase.

*There were 2 strains producing Type A β -lactamase, 2 each producing Types B, C, and D, and 2 nonproducers.

Cohen, M.A. and his coworkers demonstrated that one of the properties of cefdinir which differentiates it from other oral cephalosporins is its enhanced activity against *S. aureus*. In this study the MIC of cefdinir was 0.25 to 0.5/ μ g/mL against strains of *S. aureus* producing each of the 4 recognized staphylococcal β -lactamases A, B, C, and D, as well as a β -lactamase-nonproducing control strain as shown in Table 21. Further, the MIC of cefdinir was not altered when the inoculum was increased from 5×10^5 to 5×10^9 CFU/mL. For other oral cephalosporins, these strains were less susceptible, and in some cases the susceptibility was further diminished by increasing the inocula.

Park-Davis Pharmacological Research Cefdinir tablets (300 mg) and suspension (125 mg/5 mL) in MICs was observed for cefdinir and amoxicillin in *E. coli* CSH2, no change in the MICs of cefdinir was observed; however, a >4-fold increase into *E. coli* CSH2, no change in the MICs of cefdinir was observed; however, a >4-fold increase in MICs was observed for cefdinir and amoxicillin.

In a study by Milne, X. and colleagues, the activities of cefdinir and other β -lactams against a variety of β -lactam-resistant strains were investigated. The summary of the data appears in Table 23. Cefdinir was active against most ampicillin-resistant isolates at concentrations $\leq 1 \mu\text{g}/\text{mL}$. These included ampicillin-resistant *E. coli*, as well as most isolates of *A. pneumoniae*, *D. aerus*, *P. mirabilis*, *H. influenzae*, *A. cutthallis*, and *N. gonorrhoeae*. In several cases, cefdinir was markedly more potent than the cephalosporins ceftazidime and cephalothin. None of the compounds was highly active against several of the cephalosporins ceftazidime and cephalothin. The latter resisted the activity of the resistant *D. aerus*. The mechanisms by which the former resisted the activity of the cephalosporins were not elucidated in this study. The latter greatly owe their cephalosporin-resistance to a modified PBPs and are generally not susceptible to any β -lactam antibiotic.

In a 1989 study by Tomatsu, K., et al., cefdinir demonstrated activity against Gram-negative bacterial species producing extracellular penicillinas. These results are shown on Table 24. However, Gram-negative bacteria producing extracellular penicillinas and oxyiminocephalosporinases are also resistant to cefdinir.

In a study by Sanders, C.C. et al., a total of 65 hospital isolates of nonfastidious gram-negative bacilli resistant to various β -lactam antibiotics were tested by agar dilution for susceptibility to cefazolin. These included strains possessing well-characterized plasmid- and chromosomally treated unsuccessfully with β -lactam antibiotics. For comparative purposes cefaclor, cefuroxime, cephalaxin, ceftizime, and amoxicillin/clavulanic acid were examined in simultaneous tests. As shown in Table 25, cefazolin inhibited 72% of the study strains at concentrations of 1 μ g/mL. Only treated unsuccessfully with β -lactam antibiotics. Many have been recovered from patients mediated β -lactamases as well as permeability mutants. Many have been recovered from patients

Cefazolin tablets (300 mg) and suspension (125 mg/5 mL)

Park-Davis Pharmaceutical Research

In a study by Labia, R. et al. Cefdinir was active against the narrow-spectrum, Ambler's class A, plasmid-mediated, β -lactamases TEM-1, TEM-2, and SHV-1, as were ceftazidime, cefuroxime, and cefotaxime. Cefdinir, as other third-generation cephalosporins, showed some hydrolysis by the novel extended-spectrum β -lactamases (ESBL): TEM-3, TEM-5, SHV-2, MEN-1 and other ESBL. The relationship between the activity of cefdinir against β -lactamases increased with ceftriaxime, cefotaxime, cefuroxime, and ceftazidime, and decreased with cefixime and cefuroxime. Cefdinir, as all other third-generation cephalosporins, showed higher constitutive and inducible chromosomal β -lactamase *Escherichia coli* strains showed higher MICs to all β -lactamases (cefdinir, ceftriaxime, cefuroxime, cefotaxime, and ceftazidime) investigated. Bugges, B.M. et al. confirmed the specificity of action of β -lactamases in resistance to cefdinir: Bacteria producing the plasmid-mediated β -lactamases TEM-1, TEM-2, HMS-1, OXA-1, OXA-2, OXA-3, and SHV-1 were all susceptible to cefdinir. *Acinetobacter* isolates producing Type III and IV extended-spectrum β -lactamases were less susceptible (MIC = 4 $\mu\text{g}/\text{mL}$), and *Pseudomonas* sp producing Type V CARB-1 were highly resistant (MIC = 16 $\mu\text{g}/\text{mL}$).

β -Lactam	MIC ₅₀	MIC ₉₀	% Inhibited at 1 $\mu\text{g}/\text{mL}$	1 $\mu\text{g}/\text{mL}$	8 $\mu\text{g}/\text{mL}$	Breacpoint
Cefdinir	0.25	64	72%			
Cefixime	0.25	128	78%			
Cefuroxime	8	128	48%			
Cefotaxime	8	>128	57%			
Cephalexin	16	>128	49%			
Amoxicillin/Clavulinate	16	64	43%			

Breacpoints used were 1 $\mu\text{g}/\text{mL}$ for cefdinir and cefixime, 4 $\mu\text{g}/\text{mL}$ for cefuroxime, and 8 $\mu\text{g}/\text{mL}$ for the remaining.

TABLE 27. Activity of Cefdinir Against Bacteria Expressing Intrinsinc Resistance to

Cefdinir tablets (300 mg) and suspension (125 mg/5 mL)

Park-Davis Pharmaceutical Research

ON ORIGINAL
APPEARS THIS WAY

The organism that most frequently developed resistance was *H. influenzae*, with 4 isolates (from 3 patients). The rate of resistance development for this organism is still low at 0.7% (4/600 isolates). Resistance also developed in 1 strain each of *Streptococcus pneumoniae*, and 3 strains of *S. aureus* (from 2 patients).

Overall resistance development during adult capsule clinical studies was extremely low at 0.2% (7/3309 for MIC patients, and disk diffusion susceptibility data were available for 3447 patients. Overall resistance development during adult disk diffusion data from 3447 patients was seen in pediatric suspension studies.

The recommended cefdinir regimen (capsules) for the treatment of infection in adults and adolescents is 300 mg (173 mg/m²) BID or 600 mg (347 mg/m²) QD. To define the dose for

2. Cefdinir Pharmacokinetics

1. Assay Methods

Based on pilot plasma concentration studies performed in humans, the recommended cefdinir regimen for the treatment of infections in adults, using a capsule formulation, is either 300 mg twice a day or 600 mg once daily. The equivalent oral doses of suspension in children, ranging in age from 6 months to 12 years, are 7 mg/kg twice a day or 14 mg/kg once daily.

Cefdinir is intended to be used orally in adults and in children for community-acquired lower and upper respiratory tract infections, and for uncomplicated skin and soft tissue infections. The targeted lower respiratory diseases include: community-acquired pneumonia, acute exacerbations of chronic bronchitis, and secondary bacterial infections of acute bronchitis. The targeted upper respiratory diseases are acute suppurative otitis media, acute maxillary sinusitis, and pharyngitis/tonsillitis. This pharmacokinetic overview will focus on the concentrations of cefdinir found in respiratory tissues. The plasma and the targeted infection sites after oral administration of capsules to adults and oral suspension to children

The information in this section is taken from the NDA studies submitted by the sponsor and have not been reviewed by a Biopharmaceutical Reviewer.

A. Pharmacokinetics and Bioavailability

III. PHARMACOKINETICS AND BIOAVAILABILITY

Park-Davis Pharmacokinetic Research
Cefdinir tablets (300 mg) and suspension (125 mg/5 mL)

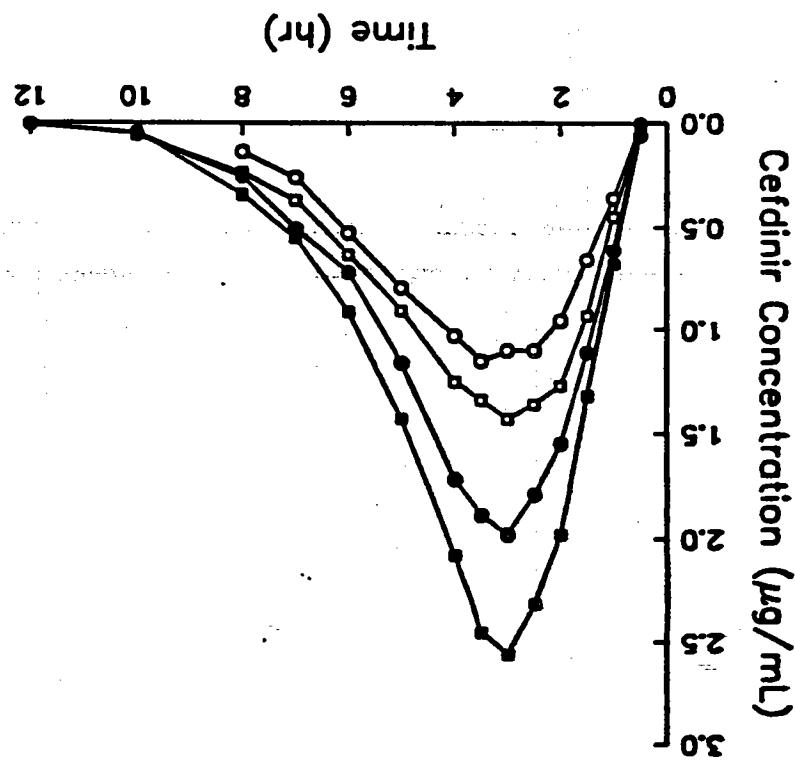

The pharmacokinetics and dose proportionality of cefdinir after a single oral doses of 200, 300, 400, and 600 mg were evaluated. Plasma cefdinir concentrations increased with dose over the 200- to 600-mg dose range (Figure 3). However, plasma concentrations increased with dose more slowly. Mean elimination half-lives of approximately 1.5 hours following all doses indicated less than predicted by a dose-proportional model. Mean maximum cefdinir concentrations were observed approximately 3 hours following all doses and then declined monodrugically. Mean elimination half-lives of approximately 1.5 hours for all doses indicated a unchanged elimination rate independent of dose (Table 32). Percent of dose recovered in urine as unchanged cefdinir in 24 hours (A_e) ranged from 12% to 19%, with the lowest recovery following administration of 600 mg. Renal clearance was constant across doses; mean values ranged from 113 to 127 mL/min. The lack of a dose-dependent change in creatinine elimination suggested that the less than dose-proportional increase in Cmax and AUC values, and reduced A_e observed at 600 mg were the result of reduced drug absorption.

a. Capsules

Phase 3 pediatric studies that would produce plasma cefdinir concentrations comparable to those observed following 300- and 600-mg capsule doses in adults, adult doses were extrapolated to pediatric doses on a mg/m² basis. These doses were then divided by 1.2 to adjust for the higher bioavailability of the suspension. Based upon pharmacokinetic considerations, pediatric doses of 7 to 14 mg/kg cefdinir suspension were recommended to adult capsule doses of 300 and 600 mg, respectively. The ability of these recommended doses to produce concentrations consistent with 300- and 600-mg doses in adults was confirmed in a pharmacokinetic study in pediatric subjects.

b. Suspension

In a Phase I safety, tolerance, and pharmacokinetic study, subjects received cefdinir as single multiple dosing.

The pharmacokinetics of cefdinir following administration of single 7- and 14-mg/kg suspension doses were evaluated in children aged 6 months to 2 years (younger) and from 2 to 12 years (older) (Study 983-23). Plasma cefdinir concentrations increased with increasing dose in both age groups (Figure 4). The overall average max value was 2.0 hours (Table 33) and mean Cmax and AUC values were similar for both age groups. Plasma cefdinir concentrations generally decreased monoenzymatically following attainment of Cmax. Mean plasma elimination t½ values following cefdinir was similar on Days 1 and 17 at all doses; thus, cefdinir does not accumulate with doses followed by 2 weeks of twice-daily doses up to 600 mg (1200 mg/day). Disposition of cefdinir was similar on Days 1 and 17 at all doses; thus, cefdinir does not accumulate with doses followed by 2 weeks of twice-daily doses up to 600 mg (1200 mg/day).

TABLE 35. Mean (Range) Plasma and Fluid/Tissue Cefdinir Concentrations and Fluid/Tissue to Plasma Ratios Following Administration of Single Cefdinir Concentrations and Lung Fluid, and middle ear fluid. These determinations are summarized in Table 35.

Cefdinir concentrations were measured in tonsil tissue, sinus tissue, bronchial mucosa, epithelial lining fluid, and middle ear fluid. These determinations are summarized in Table 35.

Cefdinir tablets (300 mg) and suspension (125 mg/5 mL)

Park-Davis Pharmaceutical Research

Cefdinir Cmax, AUC, and $t_{\frac{1}{2}}$ were elevated in subjects 65 years or older compared to subjects 18 to 30 years of age. This was attributable to an age-related decline in renal function. Thus, a dosage adjustment in elderly patients is not required unless they have intrinsic renal dysfunction.

Because cefdinir is not appreciably metabolized, studies were not performed in subjects with hepatic impairment.

Subsequent doses should be administered every other day. The conclusion of each hemodialysis session patients should receive 300-mg dose of cefdinir. Hemodialysis treatment, the recommended initial cefdinir regimen is 300 mg every other day, at from the body by dialysis, necessitating a further dosage adjustment. In patients on chronic dialysis, who should receive a 300-mg cefdinir dose once daily. Cefdinir is effectively removed (ml/min), which is approximately 10 times greater than creatinine clearance values (>30 ml/min), who should receive a 300-mg cefdinir dose once daily. Cefdinir is effectively removed only in patients with intrinsic renal dysfunction (creatinine clearance values <30 ml/min), who should receive a 300-mg cefdinir dose once daily. Cefdinir is effectively removed only in patients with intrinsic renal dysfunction (creatinine clearance values <30 ml/min).

7. Special Populations

Concomitant administration of cefdinir with iron reduced cefdinir bioavailability. The extent of the reduction was dependent on the dose of coadministered iron, being greatest (80%) in the presence of a therapeutic iron supplement (60 mg elemental iron). The effect was reduced when cefdinir and iron doses were separated by 2 hours. Therefore, it is recommended that if iron supplements are required during cefdinir therapy, cefdinir should be taken at least 2 hours after the iron supplement. The exception is iron-fortified infant formula, which did not have a clinically significant impact on cefdinir bioavailability.

Cefdinir Cmax was reduced 38% and AUC(0-∞) was reduced 44% when coadministered with Maalox TC. There was no significant effect on cefdinir pharmacokinetics if administered 2 hours before or after the antacid.

Interactions between cefdinir and several drugs were observed. As with other β-lactam antibiotics, probenecid inhibited renal tubular secretion of cefdinir, reducing cefdinir clearance and prolonging its $t_{\frac{1}{2}}$.

of 1.6 $\mu\text{g}/\text{ml}$. The plasma half-life was 1.5 hours for both the 300- and 600-mg doses.
A mean peak plasma concentration (C_{max}) of 2.87 $\mu\text{g}/\text{ml}$ was obtained from 20 healthy, fasted
subjects given a single 600-mg oral dose of cefdinir.⁽⁹⁾ A dose of 300 mg provided a mean C_{max}

I. Susceptibility Interpretive Breakpoints in Dilution Tests

The information summarized in this section is to define the standardized methods to be used by
clinical microbiology laboratories to determine the susceptibility of clinical isolates to cefdinir.

A. Clinical Laboratory Susceptibility Test Methods

IV. CLINICAL EFFICACY (CLINICAL MICROBIOLOGY)

influence on the intestinal bacterial flora.⁽⁹⁾ In this pediatric study, 7 children with infections (3
boys and 4 girls) were treated orally with 3.0 to 3.7 mg/kg per day of cefdinir fine granules 3
times a day for 4 to 14 days. The ages of the children ranged from 6 months through 12 years 7
months, and their weight distribution was 5.5 to 29.2 kg. During drug administration, some
changes were observed in the pattern of the fecal bacterial flora between subjects. Although
Enterobacteriaceae and total anaerobes were markedly decreased in other cases, predominance among
anaerobes were unchanged in these individuals. In other cases, predominance aerobes excepting
enterococci and anaerobes hardly varied. There was no case in which glucose nonfermenting
gram-negative rods or fungi became predominant species for any length of time. Although C
difficile and *C. difficile* D-1 antigens were detected in 1 and 4 cases, respectively, no relationships
were found between the number of *C. difficile* and the characteristics of the feces.

Cefdinir tablets (300 mg) and suspension (125 mg/5 mL)

To define tentative disk susceptibility guidelines for clinical trials, Jones utilized 100 bacterial

species), and 20 strains of gram-positive cocci (4 species).
the evaluation of 20 strains of enteric bacteria (14 species), 9 nonenteric gram-negative bacilli (5
diameter) and only 1 major error (false resistant zone diameter) when 5- μg disks were applied to
or 2 $\mu\text{g}/\text{mL}$.^(a) These preliminary tests revealed no very major errors (false susceptible zone
10- μg disk zone would be the best to correlate with projected MIC susceptible breakpoints of 5- or

Park-Davis Pharmaceutical Research

Disk diffusion breakpoints for these rapidly growing bacteria were confirmed by Jones, R.N. et al in a more extensive analysis.⁽⁴⁾ MCLs and zones were obtained with 403 isolates divided into the following categories: 239 strains of the family *Fusobacteriaceae* (23 species), 77 strains of *aeruginosa*, 10 strains of *C. maltophilum*, and 10 strains of *Acinetobacter* spp. The scattergram derived from these comparisons were subjected to regression and error rate bounded analyses. The investigators concluded that the preferred and proposed interpretive criteria were zone diameters of 220 mm for susceptible and 516 mm for resistant, values identical to the preliminary parameters listed above. Using these breakpoints, there were 0.6% very major errors (false-positive) and 6.4% minor errors. However, to achieve this susceptibility, 0.6% major errors (false-resistant), and 6.4% minor errors (false-susceptible). Similar problems have been observed with other oral cephalosporins such as *M. morgani*, *Fusrobacter* spp., and *P. stuartii*, as well as oxacillin-resistant *staphylococci*. An additional study by Biedenbach, D.J. and Jones, R.N., revealed an unacceptable high very major and minor error rates when cefdinir disks were tested against 100 strains of *Proteus vulgaris* and *Providencia* spp.⁽⁵⁾ The results indicated that the suggested disk diffusion

Jones stated that, application of these criteria would produce no more than 1% very major (false-susceptible) errors if methicillin-resistant *staphylococci* are considered resistant to cefdinir. The major and minor combined errors should be no greater than 5%.

Susceptible	≥ 20 mm (MCL equivalent $\leq 1 \mu\text{g}/\text{mL}$)	Resistant	≤ 16 mm (MCL equivalent $> 4 \mu\text{g}/\text{mL}$)
Intermediate	17 to 19 mm (MCL equivalent $= 2 \mu\text{g}/\text{mL}$)		

isolates to investigate the correlation of MCL and disk zone diameters.⁽⁶⁾ Microorganisms investigated included 19 strains of *E. coli*, 9 strains of *C. diversus*, 10 strains of *K. enterococcica*, 20 strains of *K. pneumoniae*, 19 strains of *C. freundii*, and 19 strains of *C. curvus*. Based on regression and error rate bounded analyses of the scattergrams obtained by plotting MCL and inhibition zone diameters obtained with 5- μg disks, the following interpretive criteria were recommended for nonfastidious bacteria:

Cefdinir tablets (300 mg) and suspension (125 mg/5 mL)

A scattergram using all US pathogens (other than *Haemophilus* spp. or *Streptococcus* spp.) tested by central laboratories during credential clinical trials is shown in Figure 6. These results confirm the disk diffusion breakpoints proposed by Jones. Very major, and minor error rates are 0.5%, 0.06 and 4.8% respectively. All organisms with interpretable errors are listed in Table 36. The majority of errors were caused by *Enterobacter* spp. and *Enterococcus* spp. When these organisms are eliminated, very major, major, and minor error rates are 0.06, 0.06, and 1.7%.

In a study by Biedenbach, D.J., et al.¹⁹, analysis relating zone diameters to NCCLS against *Morganella morgani* revealed no major error and a 1% minor error. In NCCLS table footnotes addressing this problem (footnotes j and m in table 2 of M2-A6), similar to that for *Escherichia coli* in the NCCLS table footnotes address this problem (footnotes j-susceptible) error of 5% and a minor error of 15%. The authors suggested to have a warning breakpoints for credential exceeded acceptable interpretive error rates, with very major (false-

^a Zone diameter in mm

^b Equivalent dilution breakpoint in $\mu\text{g/mL}$.

Disk diffusion susceptibility guidelines for *H. influenzae* were obtained by the investigation of 100

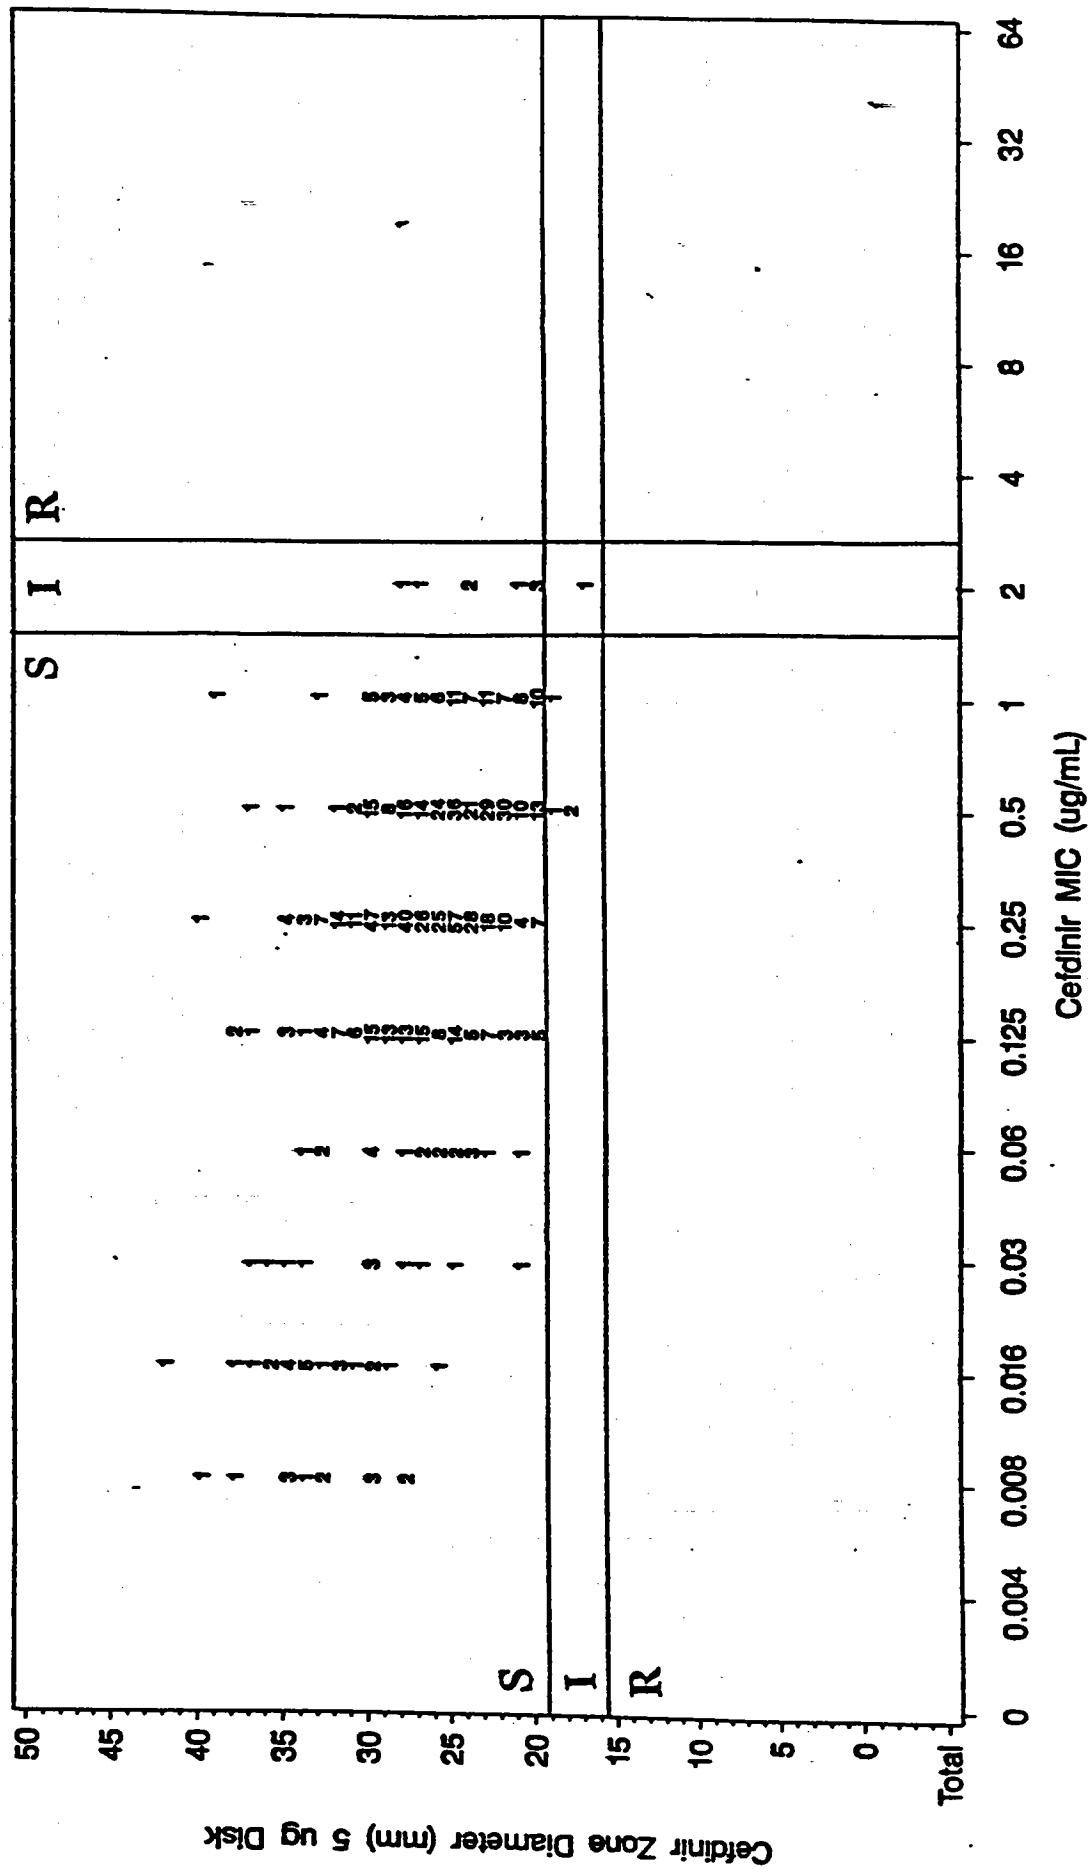

clinical strains in MIC and zone diameter susceptibility tests employing *Haemophilus* test medium.⁽⁴⁶⁾ Among the 100 isolates were 26 β -lactamase producing strains, 16 β -lactamase-negative ampicillin-resistant strains (BLNAR), and 58 ampicillin-susceptible strains. These investigators concluded that the proposed breakpoints that have been applied to rapidly growing bacteria were also applicable to *H. influenzae*. Using the above guidelines, there were 1% very major and 6% minor interpretive errors. There were no major errors. All errors were attributed to β -lactamase-negative ampicillin-resistant (BLNAR) strains.

These proposed breakpoints were confirmed by clinical trial data. The scattergram generated from all *Haemophilus* spp. from clinical trials is shown in Figure 7. The very major, major and minor error rates for all *Haemophilus* spp. combined were 0, 0, and 1.5% (12/819), and were 0, 0, and 1.7% (6/356) when considering only *H. influenzae*. None of the 6 minor errors were caused by BLNAR strains.

In a study by Barrett and Jones⁽⁴⁷⁾ the susceptibility testing interpretive criteria for cefdinir against 100 *N. gonorrhoeae* isolates was investigated on GC agar medium. Because all strains were susceptible to 0.015 $\mu\text{g}/\text{mL}$ of cefdinir, the recommended susceptible interpretive criteria were as follows: for a 5- μg disk, ≥ 31 mm (MIC correlate, $\leq 0.25 \mu\text{g}/\text{mL}$). This is the same breakpoint applied to cefixime, a structurally similar compound.

Disk diffusion breakpoints for *Streptococcus pneumoniae* were derived from studies involving a challenge set of 350 clinical isolates.⁽⁴²⁾ These included 199 penicillin-susceptible isolates (penicillin MIC $\leq 0.06 \mu\text{g}/\text{mL}$), 87 with intermediate susceptibility to penicillin (MIC 0.125 to 1.0 $\mu\text{g}/\text{mL}$), and 64 penicillin-resistant strains (MIC $\geq 2 \mu\text{g}/\text{mL}$). For definition of disk diffusion breakpoints, MIC breakpoints of $\leq 0.5 \mu\text{g}/\text{mL}$ for susceptible, 1.0 $\mu\text{g}/\text{mL}$ for intermediate, and $\geq 2 \mu\text{g}/\text{mL}$ for resistant were used. These breakpoints clearly separate 2 populations of pneumococci. Furthermore, with these breakpoints all 64 penicillin-resistant strains were resistant to cefdinir, and all penicillin-susceptible strains were susceptible to cefdinir. Of the 87 strains with intermediate susceptibility to penicillin, 68 (78%) were susceptible to cefdinir, 5 (6%) were intermediate, and 14 (16%) were resistant to cefdinir. Using regression analysis, the susceptible zone diameter breakpoint is calculated to be 23.2 mm, rounded off to 23 mm. With a resistant breakpoint of ≤ 19 mm and an intermediate range of 20 to 22 mm, there were only 2 false-susceptible disk tests (very major error rate of 0.6% or 2.6% of the 78 resistant strains), no major errors (false resistant disk tests), and 10 minor errors.

3. Comparison of MIC Broth and MIC Agar Dilution Assay Methods

In a study by Garcia, F.S, cefdinir susceptibilities were determined by agar dilution and microbroth dilution methods against 122 test strains of bacteria. The species tested were *A. anitratus*, *E. aerogenes*, *E. coli*, *E. cloacae*, *E. faecalis*, *S. aureus* (methicillin-susceptible and -resistant), *K. oxytoca*, *K. pneumoniae*, *M. catarrhalis*, *M. morganii*, *P. mirabilis*, *P. aeruginosa*, *S. epidermidis* (methicillin-susceptible), and *S. marcescens*. There was 90.9% agreement (± 1 dilution in MIC) among the results from the 2 methods. In 78 of the cases, the MICs were identical; the microbroth MIC was one-half the agar dilution MIC in 22 and twice as high in 11. In only 2 cases were >4-fold shifts encountered. Discordant results were seen most often with *E. faecalis*, with agar dilution MICs at least 4-fold higher than microbroth MICs for 5 of the 10 strains tested.

4. Cross-Resistance With Penicillin for Streptococci

Cefdinir MICs for *S. pneumoniae* increase with increasing penicillin MICs. A study conducted at Clinical Microbiology Institute used 350 strains of *S. pneumoniae* including 199 penicillin-susceptible, 87 penicillin-intermediate and 64 penicillin-resistant strains to compare cefdinir and penicillin MICs. In this study by Fuchs, et al., cefdinir clearly showed cross-resistance with penicillin when testing *S. pneumoniae*.

A study was conducted by Barry, A. et al. to assess the cross-resistance of cefdinir and penicillin when testing *Streptococcus* spp. other than *S. pneumoniae*. Four laboratories participated in testing 484 well characterized stock cultures of streptococci, each testing a different group of 121 species. Data from the four centers were combined for analysis but data with *S. pneumoniae*, viridans streptococci and beta haemolytic streptococci were analyzed separately to determine the practical utility of cefdinir disk tests. The author concluded that cefdinir disk tests are usually not needed for testing streptococci since penicillin-susceptibility can be assumed to correlate with cefdinir susceptibility. Disk diffusion tests with 10 unit penicillin disks appear to be somewhat more reliable than those 5- μ g cefdinir disks when testing pneumococci. For beta haemolytic streptococci, a 5- μ g cefdinir disk is preferred over a penicillin disk. For viridans streptococci, a dilution test is preferred over either disk.

5. Cross-Resistance With Other Cephalosporins

The total number of strains which tested intermediate or resistant to each of the oral cephalosporins used in the >5000 isolate study are shown in Table 38 (organisms that were not speciated and *Pseudomonas* spp. and *Enterococcus* spp. were deleted due to space considerations). Also, a cross-resistance plot of cefdinir vs. cephalexin from pathogens isolated from clinical trials (adult and pediatric skin infections) is shown in Figure 8. There is a general agreement of resistance, but a class disk cannot be used to determine the susceptibility to cefdinir.

6. Quality Control Studies

a. Quality Control Ranges for Dilution Susceptibility Tests

Based on the data discussed in this section, the ranges for the quality control organisms listed in Table 39 are proposed for dilution susceptibility testing with cefdinir.

TABLE 39. Quality Control Ranges for Dilution Tests (NCCLS-Approved)

Organism	Quality Control Ranges ($\mu\text{g/mL}$)
<i>E. coli</i> ATCC 25922	0.12 to 0.5
<i>S. aureus</i> ATCC 29213	0.12 to 0.5
<i>H. influenzae</i> ATCC 49766	0.12 to 0.5
<i>S. pneumoniae</i> ATCC 49619	0.03 to 0.25

Microbroth dilution MIC quality control ranges were determined for nonfastidious bacteria in cation-adjusted Mueller-Hinton broth (CAMHB). The test organisms were: *S. aureus* ATCC 29213, *E. coli* ATCC 25922, *E. faecalis* ATCC 29212, and *P. aeruginosa* ATCC 27853. Unique test lots of trays were prepared by each of the 6 participating medical centers, and a common lot of trays was prepared for all by the coordinating laboratory as an interlaboratory control. Five tests were run at each center with the common lot, and 20 tests were performed with each of the 6 unique lots. The results of these tests are summarized in Table 40. Based on these data, the above MIC ranges, as presented in Table 39 are proposed for *E. coli* ATCC 25922 and *S. aureus* ATCC 29213. Due to the high MICs obtained, *E. faecalis* ATCC 29212 and *P. aeruginosa* 27853 are not recommended for cefdinir quality control testing. In addition, cefdinir is not intended to treat infections caused by these organisms.

MIC quality control guidelines for *Haemophilus influenzae* ATCC 49766 were determined by microbroth dilution in Haemophilus Test Medium (HTM). A common lot of trays utilizing 8 different lots of HTM broths were prepared and distributed to 6 different laboratories. One hundred twenty MICs were generated at each laboratory. Based on the results shown in Table 40, a range of 0.12 to 0.5 $\mu\text{g/mL}$ is being proposed by the sponsor.

Testing with *H. influenzae* ATCC 49247 was also conducted. As shown in Table 40, results with this strain are not as reproducible when compared with results from *H. influenzae* ATCC 49766. Variable results are also seen with several other cephalosporins with this strain. Therefore, *H. influenzae* ATCC 49247 was not recommended by the sponsor for cefdinir quality control testing.

Agar dilution MICs were performed (Table 40) with cefdinir against *N. gonorrhoeae* ATCC 49226 in a standard multilaboratory study protocol to define quality control guidelines using GC agar from 3 different manufacturers. The common-lot results revealed a technical variation by 1 participating laboratory; that laboratory's data were therefore excluded from unique-lot analysis. The results support a quality control MIC range of 0.008 to 0.03 $\mu\text{g}/\text{mL}$ when cefdinir is tested against this organism in agar dilution susceptibility tests.

MIC quality control guidelines for *Streptococcus pneumoniae* ATCC 49619 were determined by microbroth dilution in CAMHB + LHB. All values fell into the MIC range of 0.06 to 0.25 $\mu\text{g}/\text{mL}$, with an apparent bimodal distribution between 0.06 and 0.12 $\mu\text{g}/\text{mL}$. Therefore, a 4-dilution range of 0.03 to 0.25 $\mu\text{g}/\text{mL}$ is proposed by the sponsor.

^b Organism not recommended for cefdinir quality control testing.

• Not applicable - 8 common lots were used by all participating laboratories.

b. Quality Control Ranges for Disk Diffusion Susceptibility Tests

Multilaboratory studies were performed to determine quality control guidelines for 5- μg cefdinir disks for *S. aureus* ATCC 25923, *E. coli* ATCC 25922, *H. influenzae* ATCC 49766, *H. influenzae* ATCC 24927, *N. gonorrhoeae* ATCC 49226, and *S. pneumoniae* ATCC 49619. Based on the test results described below, the disk quality control ranges in Table 41 have been

proposed for cefdinir.

TABLE 41. Quality Control Guidelines for Disk Diffusion Susceptibility Tests

Organism	Quality Control Ranges (Zone Diameter in mm)
<i>S. aureus</i> ATCC 25923	25 to 32
<i>E. coli</i> ATCC 25922	24 to 28
<i>H. influenzae</i> ATCC 49766	24 to 31
<i>N. gonorrhoeae</i> ATCC 49226	40 to 49
<i>S. pneumoniae</i> ATCC 49619	26 to 31

S. aureus and *E. coli* were tested on Mueller-Hinton agar. Six lots of disks and 6 lots of culture media were obtained from several manufacturers, and the results of these studies were generated in 6 clinical microbiology laboratories. Each of the 6 participant laboratories performed 20 replicate tests with a unique lot of medium and 5 replicate tests with a lot of medium common to all laboratories. Results with the common lot from each laboratory were compared for significant variation. The statistic for determining zone diameter ranges is the overall median \pm one half of the median of the individual laboratory ranges and/or an interval containing 95% of test values. The zone diameters of the different lots of disks did not vary significantly, and the quality control results with reference antimicrobials revealed that all lots of media were performing within NCCLS prescribed limits.

In tests with *E. coli*, the median of 450 data points was 26 mm, with a 95% confidence limit range of 24 to 23 mm encompassing 98.9% of the values.

In tests with *S. aureus*, 375 test values contributed to the database because of the large variation seen between laboratories, and because the quality control data generated at Park-Davis and collected from central laboratories testing cefdinir clinical trial isolates differed from the results from this study, a second multi-lab study was conducted in 1996 to confirm QC ranges for this organism.

Six lots of MH agar from 4 manufacturers were tested. Two participants were assigned one of 5 unique lots and a sixth lot was common to all ten laboratories. Two lots of cefdinir disks were used and cefuroxime was used as a control. No differences were seen between cefdinir disk lots,

Park-Davis Pharmaceutical Research

Cefdinir tablets (300 mg) and suspension (125 mg/5 mL)

and no lot-to-lot variability was seen between MH agars. A range of 25-31 mm was proposed by the investigator and includes 97% of the data.

One central lab's data agree with the results from the first multi-lab study, the cause of the discrepancy between the first and second multi-lab studies is unclear. However, the results of the recent ten-lab study reflect results from media currently available, and rather clearly define a range of 25-31 mm. The sponsor states that if, this range was increased by 1 mm, the majority of the "real world data" would be included. Therefore, the sponsor proposes an 8 mm range of 25-32 mm for quality control testing of *S. aureus* ATCC 25923 with cefdinir. This reviewer sees no problem with accepting these limits.

Ranges for *H. influenzae* ATCC 49766 were determined using 7 lots of HTM agar and 2 lots of disks. Six different laboratories generated 280 zone diameters. All but 2 values were in the selected range of 24 to 31 mm. The median was 27 mm, and 99.3% of the values were within the proposed range.

Testing was also conducted with *H. influenzae* ATCC 49247. As with several other cephalosporins, disk diffusion zones are not as reproducible with this strain, when compared to *H. influenzae* ATCC 49766. Therefore, the sponsor does not recommend *H. influenzae* ATCC 49247 for cefdinir quality control testing.

A similar study design yielded 300 unique-lot zone diameters with *N. gonorrhoeae* ATCC 49226 on GC agar. One of the 6 laboratories was out of range with all test drugs with the common lot of media. Results for this laboratory were not used for the final analysis. A range of 41 to 48 mm covered 94.0% of the values, and was suggested by the study coordinator (Dr R. Jones) as a possible range. However, the range of 40 to 49 mm was approved by the NCCLS in order to included 99.7% of the data.

S. pneumoniae ATCC 49619 was tested on MHA supplemented with 5% defibrinated sheep blood. There were 2 disk lots and 6 lots of Mueller-Hinton blood agar used to generate 350 zone diameters. All but 2 were within the range of 26 to 31 mm. Thus, the selected range of 26 to 31 mm covered 99.7% of all data; the median was 28 mm.

B. Bacteriological Efficacy

1. Summary of Clinical Trials

Sixteen clinical studies were conducted in order to determine the safety and efficacy of cefdinir in treating the following infections:

- Pharyngitis/Tonsillitis
- Acute Suppurative Otitis Media
- Acute Maxillary Sinusitis
- Uncomplicated Skin and Skin Structure Infections
- Community-Acquired Pneumonia
- Acute Exacerbations of Chronic Bronchitis
- Secondary Bacterial Infections of Acute Bronchitis

Capsule (adult) and suspension (pediatric) formulations were studied. In most protocols, dosages included 600 mg QD and 300 mg BID for the capsule formulation, or 14 mg/kg QD and 7 mg/kg BID for the suspension formulation. All studies tested a 10-day dosing schedule, except for pharyngitis studies which used 10-day and 5-day dosing for cefdinir. A summary of all pivotal and supportive clinical studies are shown in tables 42 and 43. A total of 11,163 patients were enrolled in these studies.

983-11	Otitis Media	Non-US	Cefdinir 14 mg/kg QD × 10d Cefdinir 7 mg/kg BID × 10d Amox/Clav 13.3 mg/kg TID × 10d	752

NA = North America; US = United States; amox/clav = amoxicillin/clavulanate; PenV = penicillin V-K.

2. Correlation of Interpretive Criteria With Therapeutic Outcome

If interpretive breakpoints are accurate, susceptibility test results should predict the therapeutic efficacy of an antibiotic. To validate proposed cefdinir interpretive breakpoints, bacteriologic eradication and clinical cure rates obtained during clinical studies were examined for correlation with MIC and disk diffusion results.

For the analyses in this section, the sponsor has included all clinically and microbiologically evaluable cefdinir-treated patients plus patients that had a baseline isolate which was intermediate or resistant to cefdinir or the comparative agent (ie, all "breakpoint evaluable" patients). Data from both monomicrobial and polymicrobial infections were used. All adult studies were conducted using a capsule formulation, and pediatric studies were conducted using a suspension formulation.

All susceptibility determinations were performed according to NCCLS methodologies. The majority of susceptibility testing for cefdinir clinical studies was performed by central laboratories. MICs were

determined by broth microdilution using dehydrated trays manufactured by Sensititre®, and 5- μ g cefdinir disks were used for disk diffusion testing. Interpretive breakpoints used for clinical trial entry and patient evaluability for all pathogens isolated in US and International clinical studies are shown in Table 43. These breakpoints are used for all analyses (for fastidious and nonfastidious organisms) in this section.

TABLE 43. Interpretive Breakpoints

	Susceptible	Intermediate	Resistant
MIC	$\leq 1 \mu\text{g/mL}$	$2 \mu\text{g/mL}$	$\geq 4 \mu\text{g/mL}$
Disk Diffusion	$\geq 20 \text{ mm}$	17-19 mm	$\leq 16 \text{ mm}$

Barry and colleagues selected *S. pneumoniae* cefdinir MIC breakpoints different than those listed above (See page 66 of this review). However, these studies were completed near the conclusion of clinical trials. A complete discussion of interpretive criteria for *S. pneumoniae* can be found on page 114 of this review.

Tables 44 to 50 show overall trends in the data demonstrating that the above interpretive breakpoints serve as good predictors of therapeutic outcome for all target species. There is a direct correlation between a susceptible MIC or disk diffusion result and both bacterial eradication and clinical cure rates. As seen in Table 44, when all organisms and both cefdinir formulations (capsule and suspension) are considered, susceptible MIC and disk diffusion results correspond with 89.0% and 89.1% bacterial eradication rates, respectively. Similarly, 86.2% and 85.9% clinical cure rates are seen with susceptible MIC and disk diffusion results, respectively.

Correlation between susceptible results and positive therapeutic outcome was generally uniform between cefdinir capsule and suspension studies (Tables 45-50). One exception is the lower eradication and clinical cure rates seen in pediatric studies for *Haemophilus* spp and *S. pneumoniae* as compared with those seen in adult studies. For data from susceptible MICs, the eradication and clinical cure rates for *Haemophilus* spp in pediatric (suspension) studies were 64.4% and 67.2% as compared to 84.6% and 78.2% in adult (capsule) studies. Similarly, the eradication and clinical cure rates for *S. pneumoniae* in pediatric studies were 60.3% and 61.3%, as compared to 93.4% and 85.0% in adult studies (Tables 46 and 47). Identical trends were seen with disk diffusion results (Tables 49 and 50). The majority of *Haemophilus* spp isolates (96%) and *S. pneumoniae* isolates (86%) from pediatric suspension studies were isolated from patients with otitis media. These results may reflect differences in pathophysiology between otitis media and other indications, or it could reflect the formulation differences between the suspension and the capsule, or it could be due to low concentrations of cefdinir in the middle ear fluid, in fact as it was stated in Table 35, the mean (range) concentration of cefdinir in the middle ear fluid was

0.23 µg/mL (0.0-0.94 µg/mL) for the 7 mg/kg dose and it was 0.63 µg/mL (0.0-1.42 µg/mL) for the 14 mg/kg dose which is well below the MIC₅₀ susceptible breakpoint of \leq 1 µg/mL. This issue needs to be further addressed by the pharmacologist and the medical officer. A lower eradication and clinical cure rates also were seen for these organisms with the comparative agent used in the otitis media study (amox/clav).

Park-Davis Pharmaceutical Research

Cefdinir tablets (300 mg) and suspension (125 mg/5 mL)

Correlation between susceptible MIC and disk diffusion results and positive therapeutic outcome was also consistent between QD and BID dosing regimens for both suspension and capsule formulations, and between indications (with the exception of otitis media discussed previously).

Additionally, results were generally uniform among bacterial species. Therapeutic outcome, by formulation and by individual MICs and zone diameters for key pathogens (defined as pathogens isolated 10 or more times during clinical studies and intended for inclusion in cefdinir labeling) can be found in Tables 51 through 54. When compared with other organisms, susceptible determinations correspond to lower eradication and clinical cure rates for *Haemophilus* spp (in both capsule and suspension studies), and *S. pneumoniae* (in suspension studies). However, the sponsor states that when numbers are sufficient for statistical analysis, eradication and clinical cure rates for these organisms are equivalent to the comparative agent in all studies.

As seen in Table 44, there is an overall trend for lower eradication and cure rates with intermediate and resistant isolates. Specifically there were 153/3953 (3.9%) isolates that had resistant or intermediately resistant MICs to cefdinir (186/4098, 4.5% by disk diffusion). Among these isolates 127/153 (83%) were eradicated as compare to an eradication rate of 89% for the isolates with susceptible MICs. The cure rates were also lower for isolates with intermediate and resistant MICs (107/147, 73%) as compared to isolates with susceptible MICs with cure rate of 86%.

In summary, the data show that patients were effectively treated when pathogen isolates were determined to be susceptible using the proposed MIC and disk diffusion breakpoints. When results from all isolates are combined (Table 44), susceptible MICs and disk diffusion interpretations correlate with a 89% bacterial eradication rate, and a 86% clinical cure rate. MIC and disk diffusion susceptibility tests for cefdinir serve as good predictors of therapeutic efficacy.

3. Discussion of MIC Interpretive Breakpoints for *Streptococcus pneumoniae*

Due to the emergence of penicillin-resistant strains of *Streptococcus pneumoniae*, the NCCLS began recommending in 1993 that separate interpretive breakpoints be determined for *S. pneumoniae* for all relevant antibiotics by testing large numbers of strains with varying resistance to penicillin. Because these recommendations did not exist when clinical trials with cefdinir began in 1990, the breakpoints used for all other organisms ($\leq 1 \mu\text{g/mL}$ = Susceptible, $2 \mu\text{g/mL}$ = Intermediate, and $\geq 4 \mu\text{g/mL}$ = Resistant) were used as well for *S. pneumoniae*.

In 1994, Barry, et al, tested cefdinir against 350 strains of *S. pneumoniae* with varying penicillin resistance levels (see discussion on page 69

of this review). Interpretive breakpoints 1 dilution lower than those recommended for all other organisms were suggested for the interpretation of *S. pneumoniae* cefdinir MIC data ($\leq 0.5 \mu\text{g/mL}$ = Susceptible, $1 \mu\text{g/mL}$ = Intermediate, and $\geq 2 \mu\text{g/mL}$ = Resistant). According to the sponsor, when these breakpoints were applied, all 199 penicillin-susceptible strains tested susceptible to cefdinir and all 64 penicillin-resistant strains tested resistant to cefdinir. Of the 87 strains with intermediate susceptibility to penicillin, 68 (78%) tested susceptible, 5 (6%) tested intermediate, and 14 (16%) tested resistant to cefdinir.

As seen in Table 55, because of the small number of relevant isolates in the resistant and intermediate categories, this analysis is not significantly affected when the lower breakpoints suggested by Barry are used.

TABLE 55. Correlation Between Therapeutic Outcome and Different Interpretive Criteria for *Streptococcus pneumoniae* Cefdinir Capsule- and Suspension-Treated Patients

Organism	Cefdinir Susceptibility	Pathogen Eradication Rate		Clinical Cure Rate	
		No. of Pathogens Eradicated	% Eradicated	No. of Patients Cured	% Cured
<i>Streptococcus pneumoniae</i>	R ($\geq 4 \mu\text{g/mL}$)	7/8	87.5	6/8	75.0

	I ($1 \mu\text{g/mL}$)	7/9	87.5	7/8	87.5
	S ($\leq 0.5 \mu\text{g/mL}$)	287/331	86.7	255/319	79.9

S = Susceptible; I = Intermediate; R = Resistant.

Clinical trial data were also analyzed based on penicillin susceptibility of *S. pneumoniae* isolates.

Penicillin MICs for *S. pneumoniae* were not routinely determined during clinical trials, but all available isolates (297) were tested after the conclusion of the studies. Of these 297, only 24 isolates from cefdinir-treated patients were found to be penicillin-intermediate or -resistant. Penicillin MICs for all cefdinir-treated patients with penicillin-intermediate and -resistant isolates and corresponding cefdinir

MICs and therapeutic outcomes are shown in Table 56.

* Study number-site number-patient number

^b S = Sensitive (MIC $\leq 0.06 \mu\text{g/mL}$); I = Intermediate (MIC = 0.1-1 $\mu\text{g/mL}$); R = Resistant (MIC $\geq 2 \mu\text{g/mL}$).

In addition to the patients described above, 1 cefdinir-treated patient with otitis media (983-10-4-21) had an oxacillin-resistant *S. pneumoniae* isolated at baseline (zone diameter 13 mm). A penicillin MIC was not determined. Follow-up tympanocentesis proved that this organism was eradicated.

A summary of the therapeutic outcome for all cefdinir-treated patients with penicillin-intermediate and -resistant strains of *S. pneumoniae* is shown in Table 57. Response to cefdinir treatment for patients with penicillin-intermediate isolates was good with 15 of 17 strains eradicated and 15 of 17 patients cured clinically. Six of 7 penicillin-resistant strains were eradicated and 5 of the 7 patients were clinically cured.

TABLE 57. Pathogen Eradication and Clinical Cure Rates of Penicillin-Intermediate and -Resistant Strains of *Streptococcus pneumoniae* All Cefdinir-Treated Patients

Treatment Group	Penicillin Susceptibility	Pathogen Eradication Rate		Clinical Cure Rate	
		No. of Pathogens Eradicated	% Eradicated	No. of Patients Cured	% Cured
Cefdinir 600 mg QD	R ($\geq 2 \mu\text{g/mL}$)	0/1	0	0/1	0
	I (0.1-1 $\mu\text{g/mL}$)	5/5	100	4/5	80
	S ($\leq 0.06 \mu\text{g/mL}$)	44/49	90	38/47	81
Cefdinir 300 mg BID	R ($\geq 2 \mu\text{g/mL}$)	6/6	100	5/6	83
	I (0.1-1 $\mu\text{g/mL}$)	10/12	83	11/12	92
	S ($\leq 0.06 \mu\text{g/mL}$)	101/112	90	96/111	86
Total Cefdinir	R ($\geq 2 \mu\text{g/mL}$)	6/7	86	5/7	71
	I (0.1-1 $\mu\text{g/mL}$)	15/17	88	15/17	88
	S ($\leq 0.06 \mu\text{g/mL}$)	145/161	90	134/158	85

S = Susceptible; I = Intermediate; R = Resistant.

According to the sponsor, although the clinical data show that cefdinir effectively eradicates penicillin-intermediate and -resistant strains of *S. pneumoniae* in many cases, the numbers are too small to make any definitive conclusions regarding treatment of penicillin-intermediate and -resistant strains with cefdinir, or to confirm either the *S. pneumoniae* interpretive breakpoints used during cefdinir clinical trials or those suggested by Barry. Like all cephalosporins, cefdinir shows cross-resistance with penicillin. To avoid possible therapy failures due to penicillin-resistant strains, the most conservative approach would be to suggest that only strains that are penicillin-susceptible be treated with cefdinir until additional data are available.

C. *In Vitro* Studies Conducted During Clinical Trials

1. *In Vitro* Susceptibility Summary

Based on achievable plasma concentrations, the following MIC interpretive breakpoints have been proposed for cefdinir: Susceptible, MIC $\leq 1 \mu\text{g/mL}$; Intermediate, MIC = $2 \mu\text{g/mL}$; and Resistant, MIC $\geq 4 \mu\text{g/mL}$. Using the above interpretive criteria, cefdinir showed good in vitro activity against most of the pathogens encountered during clinical studies. According to the sponsor, of the 8061 clinical trial isolates for which a cefdinir MIC was determined at baseline, 95% were susceptible to cefdinir, with MIC

values $\leq 1 \mu\text{g/mL}$. Data for the most commonly encountered pathogens are summarized in Table 58.

Cefdinir was active against most gram-positive bacteria including *S. aureus* ($\text{MIC}_{90} = 0.5 \mu\text{g/mL}$), *Streptococcus agalactiae* ($\text{MIC}_{90} = 0.125 \mu\text{g/mL}$), *S. pneumoniae* ($\text{MIC}_{90} = 0.5 \mu\text{g/mL}$), and *S. pyogenes* ($\text{MIC}_{90} = 0.016 \mu\text{g/mL}$). In addition, fastidious gram-negative bacteria were susceptible with MIC_{90} s for *H. influenzae* of $1.0 \mu\text{g/mL}$, and *H. parainfluenzae* and *M. catarrhalis* of $0.5 \mu\text{g/mL}$. Included within these fastidious organisms were many β -lactamase-producing organisms. Cefdinir showed poor activity against *E. faecalis* and *Pseudomonas aeruginosa* clinical study isolates, corresponding with results obtained in earlier preclinical *in vitro* studies.

Cefdinir was also active against some of the *Enterobacteriaceae*. Ninety percent of *E. coli* and *Proteus mirabilis* isolates were susceptible to cefdinir at concentrations of $0.5 \mu\text{g/mL}$, and 90% of *K. pneumoniae* and *Klebsiella oxytoca* isolates were susceptible at $0.25 \mu\text{g/mL}$. Cefdinir showed poor activity against *Enterobacter* spp. MIC_{90} s for these isolates ranged from $2.0 \mu\text{g/mL}$ for *E. agglomerans* to $16.0 \mu\text{g/mL}$ for *E. cloacae*. Cefdinir was also inactive against the *Serratia* spp. ($\text{MIC}_{90} = 16.0 \mu\text{g/mL}$).

2. Comparison of *In Vitro* Preclinical and Clinical Trial Data for Pathogens Included in Cefdinir Labeling

A comparison of cefdinir MIC results, for all organisms (that were included in cefdinir labeling by the sponsor), from preclinical *in vitro* studies and from clinical trials are shown in Table 59. According to the sponsor, only organisms that were considered pathogens for the disease state from which they were isolated were included in the clinical trial data analysis.

Cefdinir MIC results were roughly similar from preclinical studies and clinical trials for the isolates for which complete data was available. However, the MIC_{50} for *Staphylococcus epidermidis* was higher from clinical trials when compared with that determined in preclinical studies (16 vs 4 $\mu\text{g}/\text{mL}$ for isolates where methicillin susceptibility is unknown). According to the sponsor, because only organisms that were considered pathogens for the disease state from which they were isolated were used in the analysis, the number of *S. epidermidis* isolates in the clinical trial data was very low ($N = 14$). When all *S. epidermidis* isolates ($N = 229$) were included in the calculation, regardless of whether or not they were considered pathogens, the MIC_{50} was 2.0 $\mu\text{g}/\text{mL}$, and the MIC_{90} was 0.06 $\mu\text{g}/\text{mL}$. Also, the clinical trial data included all isolates regardless of oxacillin susceptibility, which results in a higher MIC_{50} for this organism.

From the microbiological perspective, the *in vitro* data shown in Table 59, and the pathogen eradication and clinical cure rates seen in clinical trials, the following organisms are candidates for inclusion in the "INDICATIONS AND USAGE" section of the cefdinir labeling: *Staphylococcus aureus* (methicillin-susceptible strains), *Streptococcus agalactiae*, *S. pneumoniae* (penicillin-susceptible strains), *S. pyogenes*, *Escherichia coli*, *Klebsiella pneumoniae*, *H. influenzae* (including β -lactamase producing strains), *H. parainfluenzae* (including β -lactamase producing strains), and *Moraxella catarrhalis* (including β -lactamase producing strains).

The safety and effectiveness of cefdinir has been evaluated in clinical trials and is currently under review. The results suggest that cefdinir exhibits *in vitro* MICs of 1 $\mu\text{g}/\text{mL}$ or less against $\geq 90\%$ of the strains of the following organisms: methicillin-susceptible strains of *Staphylococcus epidermidis*, viridans group streptococci, *Citrobacter diversus*, and *Proteus mirabilis*. These organisms should be included in the *in vitro* section of the cefdinir labeling.

* MIC₅₀ and MIC₉₀ not determined for <10 isolates

V. CONCLUSIONS

- Cefdinir is a new cephalosporin with a good *in vitro* spectrum against gram-negative and -positive bacteria. The MIC₅₀ for common respiratory tract and skin and skin structure pathogens including methicillin-susceptible staphylococci, streptococci, *Moraxella*, *Haemophilus*, *Escherichia coli*, and *Klebsiella pneumoniae* is ≤1.0 µg/mL.
- Cefdinir is especially effective against methicillin-susceptible *Staphylococcus aureus*. This enhanced activity is due to cefdinir's relative stability to the β-lactamases produced by staphylococci
- Cefdinir is rapidly absorbed, with maximal plasma concentrations occurring 2 to 4 hours postdose. Plasma cefdinir concentrations increase with dose, but changes are less than dose-proportional. Mean cefdinir C_{max} is 1.6 µg/mL following a single 300-mg capsule dose and 2.9 µg/mL following a single 600-mg capsule.
- Cefdinir penetrates into suction-induced skin blister fluid, tonsil tissue, bronchial mucosa, and epithelial lining fluid, in concentrations equal or greater than the MICs of the usual pathogens at these sites. However, cefdinir penetrates into sinus tissue, and middle ear effusion in concentrations

generally less than the MICs of the usual pathogens at these sites. Cefdinir is not detected in the milk of nursing women.

- Cefdinir shows excellent β -lactamase stability to common gram-negative β -lactamases of the penicillinase type. Against cephalosporinase-type β -lactamases, a varied response (moderate to good) is observed and against oxyiminocephalosporinases, poor to fair stability is seen.
- Cefdinir MICs are generally stable to medium and pH changes, serum and urine effects, and addition of 5% CO₂ atmosphere. Activity against *Enterococcus faecalis* is enhanced in MHA with 5% sheep blood.
- Cefdinir shows good *in vitro* activity against the majority of gram-negative and gram-positive organisms isolated during clinical trials. Ninety percent of the 8061 clinical trial isolates are susceptible to cefdinir at concentrations of $\leq 0.5 \mu\text{g/mL}$, and 95% are susceptible at $\leq 1.0 \mu\text{g/mL}$. *Enterococcus* spp., *Enterobacter* spp., and *Pseudomonas aeruginosa* clinical trial isolates are resistant to cefdinir with MIC₉₀s ranging from 2.0- 16 $\mu\text{g/mL}$.
- Interpretive breakpoints proposed by the sponsor for nonfastidious and *Haemophilus* spp. are as follows:

	Susceptible	Intermediate	Resistant
MIC	$\leq 1 \mu\text{g/mL}$	$2 \mu\text{g/mL}$	$\geq 4 \mu\text{g/mL}$
Disk Diffusion	$\geq 20 \text{ mm}$	17-19 mm	$\leq 16 \text{ mm}$

Using these proposed susceptible interpretive breakpoints for cefdinir, MIC and disk diffusion results correlate with positive therapeutic outcomes for both capsule and suspension cefdinir formulations. When results for all isolates are combined, susceptible MIC and disk diffusion interpretations correlate with an 89% bacterial eradication rate and an 86% clinical cure rate. In general, the correlation between susceptible results and positive therapeutic outcome was consistent between the capsule and suspension formulations, between QD versus BID dosing, and among bacterial species. Thus the data show that patients were effectively treated when isolates were judged susceptible based on the proposed breakpoints. The proposed breakpoints may stand as is with the exception of *Haemophilus* spp. which will have only susceptible breakpoint due to lack of >20 resistant isolates.

- Lower eradication and clinical cure rates are seen with intermediate and resistant isolates. However, the majority of these isolates responded to cefdinir therapy regardless of these classifications.

- Clinical data show that cefdinir eradicates penicillin-intermediate and -resistant strains of *S. pneumoniae* in many cases, but the numbers of isolates from clinical trials are too small to confirm interpretive breakpoints for this organism. Cefdinir shows cross-resistance with penicillin when testing *S. pneumoniae*. To avoid possible therapy failures due to penicillin-resistant strains, the most conservative approach would be to suggest that only penicillin-susceptible strains be treated with cefdinir until additional data are available.
- No testing for *Neisseria gonorrhoeae* is needed since the sponsor is not seeking an indication for treatment of this organism.
- The quality control ranges shown in Table 60 have been developed under standardized conditions for quality control of MIC and disk diffusion testing with cefdinir. These ranges may be used by the clinical laboratories as they stand.

TABLE 60. Quality Control Ranges for Cefdinir

Organism	MIC range ($\mu\text{g/mL}$)	Disk Diffusion Range (mm)
<i>E. coli</i> ATCC 25922	0.12-0.5	24-28
<i>S. aureus</i> ATCC 29213	0.12-0.5	NA
<i>S. aureus</i> ATCC 25923	NA	25-32
<i>H. influenzae</i> ATCC 49766	0.12-0.5	24-31
<i>S. pneumoniae</i> ATCC 49619	0.03-0.25	26-31

NA = Not applicable.

- The rate of resistance development to cefdinir during clinical trials was extremely low at 0.2%. The organism that most frequently developed resistance was *Haemophilus influenzae*, with a resistance development rate of 0.5%.
