# Clinical Pharmacology Considerations for Antibody-Drug Conjugates

## Guidance for Industry

### *DRAFT GUIDANCE*

**This guidance document is being distributed for comment purposes only.**

Comments and suggestions regarding this draft document should be submitted within 90 days of publication in the *Federal Register* of the notice announcing the availability of the draft guidance. Submit electronic comments to <https://www.regulations.gov>. Submit written comments to the Dockets Management Staff (HFA-305), Food and Drug Administration, 5630 Fishers Lane, Rm. 1061, Rockville, MD 20852. All comments should be identified with the docket number listed in the notice of availability that publishes in the *Federal Register*.

For questions regarding this draft document, contact (CDER) Office of Clinical Pharmacology Guidance and Policy at [CDER\\_OCP\\_GPT@fda.hhs.gov](mailto:CDER_OCP_GPT@fda.hhs.gov) or (CBER) Office of Communication, Outreach and Development, 800-835-4709 or 240-402-8010.

3                                   **Guidance for Industry<sup>1</sup>**  
4

5  
6 This draft guidance, when finalized, will represent the current thinking of the Food and Drug  
7 Administration (FDA or Agency) on this topic. It does not establish any rights for any person and is not  
8 binding on FDA or the public. You can use an alternative approach if it satisfies the requirements of the  
9 applicable statutes and regulations. To discuss an alternative approach, contact the FDA staff responsible  
10 for this guidance as listed on the title page.  
11

12  
13  
14  
15 **I. INTRODUCTION**  
16

17 This guidance provides recommendations to assist industry and other parties involved in the  
18 development of antibody-drug conjugates (ADCs) with a cytotoxic small molecule drug or  
19 *payload*. Specifically, this guidance addresses the FDA’s current thinking regarding clinical  
20 pharmacology considerations and recommendations for ADC development programs, including  
21 bioanalytical methods, dosing strategies, dose- and exposure-response analysis, intrinsic factors,  
22 QTc assessments, immunogenicity, and drug-drug interactions (DDIs).<sup>2</sup>  
23

24 This guidance specifically outlines clinical pharmacology considerations of ADC development  
25 programs and references other relevant guidances when appropriate.<sup>3</sup> ADCs are subject to all  
26 pertinent laws and regulations for biological products, including those governing product  
27 development, testing, and approval as outlined in section 351 of the PHS Act (42 U.S.C. 262).  
28 Given that ADCs include a small-molecule drug,<sup>4</sup> there are other guidances that are applicable  
29 to ADCs that would not necessarily apply to other biological products. Of note, this guidance  
30 does not focus on the development of any particular ADC, and questions about regulatory

---

<sup>1</sup> This guidance has been prepared by the Office of Clinical Pharmacology in the Center for Drug Evaluation and Research and the Center for Biologics Evaluation and Research at the Food and Drug Administration.

<sup>2</sup> This guidance provides recommendations for ADCs with a cytotoxic small molecule drug or *payload*, which, thus far, are primarily in oncology indications. The principles discussed in this guidance might not completely be applicable to the development of other types of ADCs and should be discussed with the FDA.

<sup>3</sup> We update guidances periodically. For the most recent version of a guidance, check the FDA guidance web page <https://www.fda.gov/regulatory-information/search-fda-guidance-documents>.

<sup>4</sup> The FDA considers an ADC to be a combination product composed of a biological product constituent part and a drug constituent part (see 21 CFR 3.2(e)(1); 70 FR 49848, 49857-49858 (August 25, 2005; effective November 23, 2005). As explained in Q.II.3 of the guidance for industry, *Questions and Answers on Biosimilar Development and the BPCI Act (Revision 1)*, (December 2018), the Center for Drug Evaluation and Research considers submission of a BLA under section 351 of the PHS Act to provide the more appropriate application type for ADCs.

## *Contains Nonbinding Recommendations*

*Draft — Not for Implementation*

31 requirements and development programs for a particular ADC should be addressed to the  
32 appropriate FDA review division.

33  
34 The contents of this document do not have the force and effect of law and are not meant to  
35 bind the public in any way, unless specifically incorporated into a contract. This document is  
36 intended only to provide clarity to the public regarding existing requirements under the law.  
37 FDA guidance documents, including this guidance, should be viewed only as  
38 recommendations, unless specific regulatory or statutory requirements are cited. The use of the  
39 word *should* in Agency guidance means that something is suggested or recommended, but not  
40 required.

41

42

## 43 **II. BACKGROUND**

44

### 45 **A. ADCs**

46

47 An ADC is composed of one type of small-molecule drug, also known as a payload, and an  
48 antibody or antibody fragment, conjugated together by a chemical linker. The antibody or  
49 antibody fragment (herein referred to as the antibody) is selected or engineered against a specific  
50 antigen of interest present on the target cell surface, which is ideally unique to the disease state  
51 being treated (e.g., a tumor-specific antigen). In general, when the antibody binds to its target  
52 antigen, the ADC is internalized through physiological mechanisms (e.g., endocytosis), at which  
53 point the payload is released either upon exposure to the low pH of the lysosome or by  
54 degradation of the antibody/linker by lysosomal enzymes. The released payload then exerts its  
55 effect in the targeted cell (e.g., the cells expressing the specific antigen of interest) while ideally  
56 minimizing the effect on non-targeted cells (e.g., the cells that do not express the specific antigen  
57 of interest). Given that the mechanism of action (MOA) of ADCs aims to deliver the payload  
58 directly to a specific site, the systemic exposure of the payload can be relatively low compared to  
59 use of these payloads as oral and intravenous monotherapy.

60

61 The following terminology will be used in this guidance:

62

- 63 • **ADC** – an antibody or antibody fragment (herein referred to as the antibody) conjugated  
64 to at least one payload molecule via a chemical linker (i.e., drug to antibody ratio (DAR)  
65 of at least one)
- 66
- 67 • **Total antibody** – the collection of antibodies that are both unconjugated (e.g., not  
68 conjugated to any payload molecules) and conjugated to at least one payload molecule
- 69
- 70 • **Unconjugated antibody** – a free antibody not conjugated to any payload molecules  
71 (DAR equal to 0)
- 72
- 73 • **Unconjugated small-molecule drug or payload** – a free small-molecule drug that is not  
74 conjugated to an antibody
- 75

## *Contains Nonbinding Recommendations*

*Draft — Not for Implementation*

- 76 • **Chemical linker** – the linkage between the small-molecule drug or payload and the  
77 antibody
- 78
- 79 • **Constituent parts of the ADC** – includes the total antibody and the unconjugated  
80 payload
- 81
- 82 • **Pharmacologically active metabolite** – a pharmacologically active metabolite from the  
83 metabolism of the unconjugated small molecule drug or payload that contributes to  
84 efficacy and safety. Also see FDA’s guidance entitled *Safety Testing for Metabolites*  
85 (March 2020).
- 86

### **B. Key Considerations for ADC Dosing Strategies**

87  
88  
89 ADCs combine the selectivity of an antibody for a specific target with the potency of a small-  
90 molecule drug. Therefore, selection of optimal dosing strategies for ADCs requires careful  
91 consideration of the differences between the pharmacokinetics (PK) and pharmacodynamics  
92 (PD) of the antibody and the payload. Given that payloads are cytotoxic, a relatively small  
93 increase in the systemic exposure of the payload can cause significant adverse reactions.  
94 Therefore, the toxicity of the payload is dose limiting from a safety perspective. Given these  
95 challenges, gaining a thorough understanding of the PK and PD of the ADC and its constituent  
96 parts early in development and their relationships to safety and efficacy outcomes is crucial to  
97 optimize the ADC dose. The data contributing to this understanding can include the nonclinical  
98 program.<sup>5</sup>

#### *1. Dose Selection During Clinical Development*

99  
100  
101  
102 The FDA strongly encourages broad dose-ranging in first-in-human studies for ADCs and the  
103 selection of multiple-dose levels for evaluation in early clinical development (e.g., cohort  
104 expansion in Phase I or Phase II studies) to characterize the safety and activity of the ADC.  
105 Overall tolerability in early studies should also be considered in the selection of the dosing  
106 strategies for a pivotal study or studies. Information from exposure-response analyses using data  
107 from these early clinical studies - that evaluates the relationship of the exposure of both the ADC  
108 and its constituent parts to safety and/or efficacy - can also be used to select dosing strategies for  
109 a pivotal study or studies. Furthermore, exposure-response analyses can be used to select dosing  
110 strategies for specific subsets of patients in pivotal studies (e.g., study participants with organ  
111 impairment). Additional supportive data, such as pharmacodynamic biomarker data and receptor  
112 occupancy/target engagement data, should be leveraged to help select dosing strategies for a  
113 pivotal study or studies and/or specific patient subsets.

#### *2. Considerations for Dosing Strategies for Intrinsic and Extrinsic Factors*

114  
115  
116  
117 Dose adjustments based on intrinsic and extrinsic factors (e.g., renal or hepatic impairment,  
118 DDIs) are challenging because the different constituent parts of the ADC can independently  
119 contribute to safety and/or efficacy. For example, adjusting the dose of the ADC in a specific

---

<sup>5</sup> Please see the FDA guidance entitled *S9 Nonclinical Evaluation for Anticancer Pharmaceuticals Questions and Answers* (June 2018).

## ***Contains Nonbinding Recommendations***

*Draft — Not for Implementation*

120 patient subset to match the exposure of one constituent part (e.g., usually the payload) in the  
121 overall population could lead to altered ADC exposure and, subsequently, altered efficacy.  
122 However, the impact of the intrinsic and extrinsic factors on PK, safety, and efficacy should  
123 always be evaluated in ADC development programs to inform labeling instructions for use in  
124 specific patient subsets. For example, *no dose adjustment* would be recommended for a specific  
125 population where the PK and risk-benefit profile are not expected to be significantly changed  
126 from the overall population. Conversely, labeling recommendations could include *avoid dosing*.  
127 in a specific population where adverse events are expected to increase in severity and frequency  
128 in comparison to the overall population, but the dosage cannot be adjusted without adversely  
129 impacting efficacy.

130  
131 Pharmacokinetic, efficacy, and safety information for recommendations on dose adjustments can  
132 be obtained from:

133  
134 (1) Patients with organ impairment or interacting concomitant medications enrolled in the  
135 dose escalation studies (e.g., as a staggered cohort at lower doses compared to patients  
136 with normal organ function or no interacting drug)

137  
138 (2) Patients with organ impairment or interacting concomitant medications enrolled in  
139 safety and efficacy studies

140  
141 (3) Dedicated organ impairment or DDI studies  
142

143 Of note, enrollment of patients based on various intrinsic or extrinsic factors in safety and  
144 efficacy studies should be based on the absorption, distribution, metabolism, and excretion  
145 (ADME) of the payload and the safety/efficacy profile of the ADC in early studies. Also, while  
146 human mass balance studies might not be feasible with ADCs, efforts to assess or predict human  
147 elimination pathways of the payload can include assessment of excreted metabolites in urine and  
148 feces in early clinical trials or animal studies and in vitro assays of the payload. See the relevant  
149 sections below for more information on intrinsic and extrinsic factors.

150  
151

### **III. CLINICAL PHARMACOLOGY CONSIDERATIONS**

152  
153  
154 Given that ADCs are composed of an antibody, a chemical linker, and a payload, evaluating the  
155 clinical pharmacology of ADCs can be more complex than for small or large molecules alone.

#### **A. Bioanalytical Approach**

156  
157  
158  
159 All bioanalytical methods should be validated and reported as outlined in the FDA's guidance  
160 entitled *Bioanalytical Method Validation* (May 2018). In general, beginning with first-in-human  
161 studies, the ADC, its constituent parts, and its pharmacologically active metabolites, if any,  
162 should be measured. Later in development, the ADC, its constituent parts, and its  
163 pharmacologically active metabolites that are quantifiable in systemic circulation should be  
164 measured to inform exposure-response analyses as described in section III.B Dose- and

## *Contains Nonbinding Recommendations*

*Draft — Not for Implementation*

165 Exposure-Response. Any decisions to exclude measurements of constituent parts of the ADC or  
166 pharmacologically active metabolites in later development should take into consideration:

- 167
- 168 • Their pharmacokinetic characteristics from early clinical trials (e.g., the correlation  
169 between the total antibody and ADC concentrations, the systemic exposure of the  
170 unconjugated payload and pharmacologically active metabolites)
- 171
- 172 • Relevant nonclinical pharmacology, pharmacokinetics, or safety data (e.g., nonclinical  
173 data regarding the MOA of the ADC, pharmacologic activity of the unconjugated  
174 antibody, pharmacological activity of metabolites).
- 175
- 176 • Preliminary exposure-response data on the contribution of the ADC's constituent parts to  
177 safety and/or efficacy
- 178

179 For example, if the unconjugated payload is undetectable with a sufficiently sensitive assay, the  
180 FDA may not recommend measuring the unconjugated payload. If the antibody constituent part  
181 only serves to selectively deliver the payload (i.e., acts as a carrier), and the total antibody  
182 concentrations are highly correlated to the ADC, the FDA may not recommend measuring the  
183 unconjugated antibody.

184

185 Of note, bioanalytical assays for the unconjugated payload should be sufficiently sensitive to  
186 detect small changes in systemic exposure that could be clinically meaningful. Additionally, if  
187 the antibody's target is shed into the systemic circulation to a significant extent, bioanalytical  
188 assays could be recommended to distinguish the target-unbound ADC from the target-bound  
189 ADC. See section III.B Dose- and Exposure-Response for additional information.

190

191 The following is a list of some dedicated clinical pharmacology studies that describe when the  
192 ADC, its constituent parts, and pharmacologically active metabolites, if any, should be  
193 considered for quantification via validated bioanalytical methods.

- 194
- 195 • For organ impairment studies, the ADC, the unconjugated payload, and  
196 pharmacologically active metabolites should be measured. The total antibody should be  
197 measured if mechanistically relevant. See section III.C.1 Organ Impairment for more  
198 information.
- 199
- 200 • For QTc assessments, measuring the unconjugated payload and pharmacologically active  
201 metabolites is usually sufficient. If the exposure of the unconjugated payload is low and  
202 cannot be quantified, a time-based analysis, where detection of the ADC will verify  
203 administration of the product, should be conducted. See section III.D QTc Assessment  
204 for more information.
- 205
- 206 • For DDI studies, measuring the unconjugated payload and pharmacologically active  
207 metabolites could be adequate if the bioanalytical assays exhibit a sensitivity that  
208 adequately characterizes the relatively low systemic exposure of the unconjugated  
209 payload. Also, if the antibody is expected to be mechanistically involved in a DDI either

## ***Contains Nonbinding Recommendations***

*Draft — Not for Implementation*

210 as a victim or perpetrator,<sup>6</sup> measuring the ADC or total antibody in relevant studies could  
211 also be recommended. See section III.F DDIs for more information.

212

- 213 • For pharmacokinetic comparability studies (e.g., manufacturing process changes,  
214 formulation changes), concentrations of the ADC and its constituent parts should be  
215 measured.

216

### **B. Dose- and Exposure-Response**

217

218 In addition to evaluating the dose-response relationship of the ADC, exposure-response analyses  
219 should be conducted for safety and efficacy with the ADC, its constituent parts, and  
220 pharmacologically active metabolites, if any. These analyses help support dose selection and  
221 dose adjustments as outlined by the FDA’s guidance, *Exposure-Response Relationships - Study*  
222 *Design, Data Analysis, and Regulatory Applications* (April 2003). In later development,  
223 justification can be provided for not conducting exposure-response analyses with an ADC  
224 constituent part or pharmacologically active metabolites (e.g., low systemic exposure of the  
225 payload or pharmacologically active metabolites, no pharmacological activity of the antibody,  
226 total antibody concentrations are highly correlated with that of the ADC). See sections II.B.1  
227 Dose Selection during Clinical Development and II.B.2 Considerations for Dosing Strategies for  
228 Intrinsic and Extrinsic Factors for more information.

229

230 Also, if the antibody target is known to shed into the systemic circulation to a significant extent,  
231 exposure-response analyses should only be conducted with the ADC and/or total antibody that is  
232 not bound to the shed target in circulation. Considerations for such analyses can include:

233

- 234 • The relative concentrations of the target-bound ADC compared to target-unbound (free)  
235 ADC in circulation
- 236 • Correlations between the target-bound ADC and target-unbound (free) ADC  
237 concentrations
- 238 • The potential for the target-bound ADC to retain pharmacological activity

239

### **C. Intrinsic Factors**

240

241 Intrinsic factors (e.g., renal or liver impairment, pharmacogenomics, body weight, age, gender,  
242 race) that have the potential to influence exposure of the ADC, its constituent parts, and  
243 pharmacologically active metabolite, if any, should be evaluated in either: 1) clinical studies,  
244 through population pharmacokinetic analysis; or 2) dedicated studies. Some special  
245 considerations for organ impairment and pharmacogenomics are elaborated below.

246

247

248

249

250

---

<sup>6</sup> Victim is defined as an investigational product that is a substrate of metabolizing enzymes. Perpetrator is defined as an investigational product that is an inhibitor or inducer of a metabolizing enzyme. Please see the FDA’s guidance *In Vitro Drug Interaction Studies — Cytochrome P450 Enzyme- and Transporter-Mediated Drug Interactions* (January 2020) for more information.

## Contains Nonbinding Recommendations

Draft — Not for Implementation

### 251 1. Organ Impairment

252  
253 The unconjugated payload and pharmacologically active metabolites, if any, can undergo renal  
254 or hepatic elimination. Impaired renal or hepatic function can lead to changes in unconjugated  
255 payload exposure that could alter the safety and/or efficacy profile of the ADC. Therefore, the  
256 impact of renal and hepatic impairment on the PK of the unconjugated payload should be  
257 assessed in all ADC development programs per the principles outlined in the FDA’s guidance  
258 *Pharmacokinetics in Patients with Impaired Hepatic Function: Study Design, Data Analysis, and*  
259 *Impact on Dosing and Labeling* (May 2003).<sup>7</sup>

260  
261 Assessing the effect of organ impairment on the exposure of the ADC or the total antibody could  
262 be relevant. For example, the ADC could be eliminated through the renal route if an antibody  
263 fragment is used, and the molecular weight of the ADC is less than 69 kDa. Also, altered ADC  
264 exposure has been observed in patients with hepatic impairment.<sup>8</sup>

265  
266 The sponsor should provide a rationale for including or not including the ADC, its constituent  
267 parts, and pharmacologically active metabolites, if any, in the organ impairment assessment.  
268 Recommending ADC dose adjustments for organ impairment, when appropriate, should be made  
269 by considering the pharmacokinetic, safety, and efficacy data in the target population. See  
270 sections II.B.1 Dose Selection in Clinical Development and II.B.2 Considerations for Dosing  
271 Strategies for Intrinsic and Extrinsic Factors for more information.

272  
273 A population pharmacokinetic approach can be used to assess the effects of organ impairment on  
274 the unconjugated payload, pharmacologically active metabolites, if any, and/or other ADC  
275 constituent parts if patients with organ impairment are enrolled in pivotal studies, and  
276 pharmacokinetic data coupled with safety and efficacy information in those patients are  
277 available. Specifically, the FDA recommends:

- 278
- 279 • Sufficient ADME information of the unconjugated payload, pharmacologically active  
280 metabolites and/or other ADC constituent parts, from non-clinical<sup>9</sup> and early clinical  
281 studies to inform inclusion of varying degrees of organ impairment in pivotal studies. For  
282 additional information, refer to the FDA’s guidances *Enhancing the Diversity of Clinical*  
283 *Trial Populations — Eligibility Criteria, Enrollment Practices, and Trial Designs*  
284 (November 2020) and *Cancer Clinical Trial Eligibility Criteria: Patients with Organ*  
285 *Dysfunction or Prior or Concurrent Malignancies* (July 2020).
- 286

---

<sup>7</sup> See also the FDA guidance *Pharmacokinetics in Patients with Impaired Renal Function - Study Design, Data Analysis, and Impact on Dosing* (September 2020). When final, this guidance will represent the FDA’s current thinking on this topic.

<sup>8</sup> Sun, Q, S Seo, S Zvada, C Liu, and K Reynolds, 2020, Does Hepatic Impairment Affect the Exposure of Monoclonal Antibodies?, *Clin Pharm Ther*, 107(5):1256-1262.

<sup>9</sup> Please see the FDA guidance entitled *S9 Nonclinical Evaluation for Anticancer Pharmaceuticals Questions and Answers* (June 2018).

## ***Contains Nonbinding Recommendations***

*Draft — Not for Implementation*

- 287
- 288
- 289
- 290
- 291
- 292
- 293
- 294
- 295
- 296
- 297
- Adequate pharmacokinetic sampling during pivotal studies to allow for accurate estimation of the effect of organ impairment on clearance of the unconjugated payload, pharmacologically active metabolite, and/or other ADC constituent parts. Refer to the FDA’s guidance *Population Pharmacokinetics* (February 2022) for additional information on pharmacokinetic sampling.
  - Sufficient safety and efficacy information in patients with organ impairment to understand the impact of an exposure change, if any. Of note, the number of enrolled patients with organ impairment to provide sufficient safety and efficacy information should be prospectively discussed with the FDA on a case-by-case basis.

298

299

300

301

302

Dedicated studies in subset of patients with organ impairment (e.g., a dose escalation study, a pharmacokinetic study) can also be conducted to guide dosing recommendations for these patient subsets. Whether or not to recommend - and the design of - a dedicated study is determined by characteristics of the ADC, such as:

- 303
- 304
- 305
- 306
- 307
- 308
- 309
- 310
- 311
- 312
- 313
- 314
- 315
- ADME and potential changes in the systemic exposure of the ADC and/or unconjugated payload (e.g., an expectation of a clinically significant change in the systemic exposure of the unconjugated payload could lead to a recommendation of a dedicated study)
  - The dose- or exposure-response relationship of the ADC with efficacy and of the unconjugated payload with safety (e.g., a shallow exposure-response relationship for efficacy with a steep exposure-response relationship for safety would likely allow for testing a reduced starting dose in a dedicated study without compromising the risk/benefit ratio)
  - Safety signals that can be correlated with exposure changes, detected in study participants included in efficacy and safety studies, especially those with organ impairment

### 316 2. *Pharmacogenomics*

317

318

319

320

321

322

323

324

Evaluation of genotype information on exposure or response to an ADC could be recommended as outlined in the FDA’s guidance *Clinical Pharmacogenomics: Premarket Evaluation in Early-Phase Clinical Studies and Recommendations for Labeling* (January 2013). For ADCs, a recommendation for a pharmacogenetic evaluation depends on ADME information, the systemic exposure of the unconjugated payload, and the role of the antibody in the MOA of the ADC, for example:

- 325
- 326
- 327
- 328
- 329
- 330
- 331
- 332
- Genetic variants and/or expression of the target for the antibody can affect patient response to the ADC.
  - Unconjugated payload could be metabolized or transported by metabolizing enzymes or transporters in the liver, which can exhibit functional genetic variants that impact the metabolism rate (e.g., cytochrome P450 2D6 (CYP2D6), or breast cancer resistant protein (BCRP)).

## Contains Nonbinding Recommendations

Draft — Not for Implementation

- Functional genetic variants of Fc-gamma receptors (FcγRs) can affect the binding of IgG molecules to FcγRs, leading to altered antibody-dependent cellular cytotoxicity (ADCC), which can be a contributing factor to the MOA of the ADC.

### D. QTc Assessment

An assessment of QT prolongation risk and a proposed QT assessment plan should be submitted for all ADC development programs as outlined by the FDA’s guidance *E14 Clinical Evaluation of QT/QTc Interval Prolongation and Proarrhythmic Potential for Non-Antiarrhythmic Drugs* (October 2012). In general, the unconjugated payload is the only constituent part of the ADC considered to have potential risk for QT prolongation. Therefore, the QT assessment plan for an ADC development program should consider all the factors that would be part of a QT assessment for a small-molecule drug. Any analysis recommended for the QT assessment should be determined using information about the payload’s ADME characteristics. Of note, electrocardiogram (ECG) monitoring during early clinical trials coupled with a sufficiently sensitive bioanalytical assay for the unconjugated payload could be deemed a sufficient QT assessment. If exposure of the unconjugated payload is low and cannot be quantified, a time-based analysis, where detection of the ADC will verify administration of the product, should be conducted.

### E. Immunogenicity

An immune response to an ADC can be generated to any constituent part of the ADC, including the antibody, the payload, or epitopes created by the conjugation linker. Given that ADCs generally have a relatively narrow therapeutic window, it is important to evaluate immunogenicity to ADCs and the potential impact on PK, safety and efficacy. A multitiered immunogenicity assessment should be conducted as outlined in the FDA guidances *Immunogenicity Assessment for Therapeutic Protein Products* (August 2014) and *Immunogenicity Testing of Therapeutic Protein Products — Developing and Validating Assays for Anti-Drug Antibody Detection* (January 2019), including a confirmatory assessment detecting anti-drug antibodies (ADAs) against the ADC. Additionally, it could be appropriate to develop multiple assays to measure the immune responses to the constituent parts of the ADC, such as additional epitopes or domains resulting from the conjugation of the constituent parts.

### F. DDIs

ADC development programs should include an in vitro DDI risk assessment for the unconjugated payload and pharmacologically active metabolites, if any, as both a perpetrator and a victim using both CYP enzyme- and transporter-related assays as outlined in the FDA’s guidance *In Vitro Drug Interaction Studies — Cytochrome P450 Enzyme- and Transporter-Mediated Drug Interactions* (January 2020). Based on in vitro characterization of the metabolic enzymes and transporters involved in the disposition and elimination of the payload and its pharmacologically active metabolites, payload toxicity, and/or the potential contribution to efficacy, the FDA could recommend that the sponsor conduct an in vivo DDI evaluation of the unconjugated payload as a victim. Characterizing the systemic exposure of the unconjugated

## Contains Nonbinding Recommendations

Draft — Not for Implementation

378 payload, though possibly relatively low, is important for determining its DDI potential as a  
379 perpetrator.

380  
381 In vivo DDI characterization should be conducted as outlined in the FDA’s guidance *Clinical*  
382 *Drug Interaction Studies — Cytochrome P450 Enzyme- and Transporter-Mediated Drug*  
383 *Interactions* (January 2020). Conducting an in vivo DDI characterization and developing a risk  
384 mitigation strategy due to DDIs should be based on early characterization of in vitro DDIs and an  
385 understanding of the concomitant medications of the target patient population. Additionally,  
386 physiologically based pharmacokinetic modeling could be appropriate as outlined in the FDA’s  
387 guidance *Physiologically Based Pharmacokinetic Analyses — Format and Content* (September  
388 2018).

389  
390 Of note, adequate in vivo DDI characterization could be achieved from the pivotal efficacy study  
391 when prospectively designed with the following considerations:

- 392
- 393 • Detailed classification of concomitant medications as sensitive substrates (if the  
394 unconjugated payload and/or pharmacologically active metabolites have the potential as  
395 a perpetrator based on in vitro risk evaluation), and strong or moderate inducers or  
396 inhibitors
  - 397
  - 398 • Timing of concomitant medications relative to the administration of the therapeutic  
399 product
  - 400
  - 401 • Dosing regimen and route of the concomitant medications
  - 402
  - 403 • Prespecified analysis
  - 404
  - 405 • Adequate pharmacokinetic sampling and measurement of the victim concomitant  
406 medications
  - 407

408 Also, under certain circumstances, the FDA could recommend an assessment of the DDI  
409 potential for the antibody component.<sup>10</sup> In summary, a DDI evaluation could be recommended if  
410 the ADC is administered with:

- 411
- 412 • Medications that share the same pharmacodynamic target with the ADC
  - 413
  - 414 • Medications that block or interfere with the interaction between an ADC containing an  
415 Fc region of human IgG and FcRn
  - 416
  - 417 • Immunosuppressors if the ADC’s PK are affected by immunogenicity
  - 418

419 Although there could be limitations in the ability to modify the dose of an ADC, the sponsor  
420 should seek to understand whether a drug can be safely used concomitantly with the ADC.

---

<sup>10</sup> For more information, please see the FDA guidance *Drug-Drug Interaction Assessment for Therapeutic Proteins* (August 2020). When final, this guidance will represent the FDA’s current thinking on this topic.
