INTENDED USE
Search-Cyte® Pool 0.8% Reagent Red Blood Cells is for the detection of unexpected antibodies in gel techniques.

SUMMARY AND EXPLANATION
Search-Cyte® Pool 0.8%, a pool cell of two selected human red blood cells of the blood group O, is suitable for the detection of unexpected antibodies directed against the major blood group systems in donors. The antigen typings of the pooled cells are provided on the antigenic constitution matrix that accompanies each product.

PRINCIPLE OF THE TEST
Antibodies react with red blood cells possessing the corresponding antigénic determinants. Search-Cyte® Pool 0.8% Reagent Red Blood Cells products are utilized in the gel technique for the detection of unexpected blood group antibodies.

REAGENTS
Search-Cyte® Pool 0.8% consists of a suspension (0.8 ± 0.1%) of two pooled red cells in buffered isotonic solution with added preservatives (0.010% (w/v) neomycin and 0.017% (w/v) chloramphenicol). The pool cell is prepared from two single donors: one of Rh phenotype R1R1 (CDe/cDe) and one R1R1 (cDe/CDe). The further antigens can be seen on the enclosed antigen matrix. Frozen/thawed red blood cells may have been used in this product. No U.S. standard of potency.

STORAGE AND STABILITY
- The expiration date of each lot is no longer than 61 days from the collection date of red blood cells from any donor in the lot.
- Store at 2 - 8 °C.
- Do not freeze.

QUALITY CONTROL
A known negative and a known positive control with weak reacting antibodies should be run in parallel on each day of use. Use of an autocontrol may be helpful in distinguishing autoantibodies and alloantibodies. If the autocontrol is positive, the serum may contain autoantibody and further testing may be indicated2.

RESULTS
Interpretation
Agglutination and/or hemolysis (positive reaction) of the Search-Cyte® Pool 0.8% cell indicates the presence of unexpected antibodies. Such antibodies are usually directed against the known antigens present on the screening cells, but may be directed against an antigen not indicated on the antigen matrix.

The lack of both agglutination and hemolysis (negative reaction) in the test procedure indicates the absence of antibodies to antigens contained on the reagent red blood cell.

LIMITATIONS OF PROCEDURE
1. Pooled cells are not recommended for pretransfusion tests, done in lieu of major cross-match, to detect unexpected antibodies in patient samples.
2. False positive or false negative results can occur due to contamination of test material, improper reaction temperature, improper storage of materials, improper centrifugation, omission of test reagents, or certain disease states.
3. Any modifications of the test procedures described in this instruction for use require validation by the user.
4. It is in the nature of a pool cell that the antigen dose of antigens may be reduced. The reduced antigen density leads to reduced sensitivity for the respective antigen. Therefore, the sensitivity of the pool cell may be slightly lower compared to the sensitivity of a screening cell of a two cell or three cell screening panel.
5. Due to the pool of two cells of two distinct donors, it is possible that the pool cell is positive and negative for a specific antigen, which leads in the case of a positive result in antibody screening to a double population (one part of cells agglutinating in the gel matrix, whereas the other part of the cells sediments to the bottom of the gel tube). Such a result is to be interpreted as positive.
6. If poor anti-coagulated plasma or incompletely clotted serum is used, fibrin residues may trap non-agglutinated red blood cells at the top of the gel, appearing as a pinkish or reddish layer, but the negative reaction can be interpreted as such. It is recommended to re clot the serum and repeat the test.
7. Low-incidence antigens may not be represented in the Search-Cyte® Pool 0.8% Reagent Red Blood Cells, so negative reactions with them do not always indicate absence of an antibody in the sample under study.
8. Because of the high incidence of the Fy(a+) gene in the Black population, it cannot be assumed that the phenotypes Fy(a+b+) and Fy(a-b+) in Black donors represent homozygous expressions of the Fy(a)2 or Fy(a)2 genes. Use of an autocontrol may be helpful in distinguishing between autoantibodies and alloantibodies.

SPECIMEN COLLECTION AND PREPARATION
No special preparation of the patient is required prior to specimen collection. Serum from freshly clotted blood is preferred. For optimum test results, serum should be stored at 2 - 8 °C no longer than 72 hours prior to testing; however, serum may be frozen and stored up to 5 years at -20 °C or colder and tested at a later time if necessary. Plasma samples may be used; however, use of plasma may result in failure to detect complement dependent antibodies due to its low complement activity1,2.

MATERIALS
Materials Provided
Search-Cyte® Pool 0.8% Reagent Red Blood Cells, 1x10 ml, cat. no. 213663

PROCEDURE
Both the reagent and the samples to be tested must be brought to room temperature (20 - 25 °C) prior to testing. Carefully resuspend Search-Cyte® Pool 0.8% by gentle inversion immediately prior to use. Reagent Red Blood Cells are ready-to-use. Follow the procedure outlined in the DG Gel 8 System's instructions for use.
False negative results may occur if
1. Antibody elutes from red blood cells during incubation.
2. Red blood cells and/or serum are stored improperly and lose reactivity.
3. Incubation times and/or temperatures are incorrect for proper red blood cells sensitization.
4. Plasma is used, complement-dependent hemolytic reactions may not be detected.

False positive results may occur if
1. Antibodies to antibiotics or to other ingredients in the red blood cells suspending medium used are present in the test serum.
2. In rare cases, the test serum contains an antibody directed at one of the components of the reagent diluent.
3. The formation of “rouleaux”, caused by an excess of protein in the serum, the presence of abnormal proteins, drugs, plasma expanders, etc., may cause false positive reactions².

SPECIFIC PERFORMANCE CHARACTERISTICS

- Each lot of Search-Cyte® Pool 0.8% Reagent Red Blood Cell is carefully prepared to permit detection of antibodies to the selected red blood cells antigens when used as outlined in these procedures.
- All antigen typings listed on the antigenic constitution matrix are confirmed using two sources of antisera except for those indicated on the antigenic constitution matrix enclosed with each lot.
- Identified low incidence antigens present are indicated on the antigenic constitution matrix. Direct antiglobulin tests are negative on all red blood cells.
- As with all red blood cells, the reactivity of the product may decrease during the shelf-life. The rate at which antigen reactivity is lost is partially dependent upon individual donor characteristics that are neither controlled nor predictable by the manufacturer. However, if properly stored when not in use, the reagent can be expected to perform as described throughout its shelf-life.
- For manual method, the performance of the reagents was confirmed against FDA-licensed reagents in a comparison study where reagents were tested in parallel at different clinical sites. The estimated percent agreements and their lower limits of 95% one-side confidence interval for all sites combined are indicated on the table below.

### Overall Statistical Analysis Results of the comparison study

<table>
<thead>
<tr>
