INTERCEPT® Blood System for Platelets –Dual Storage (DS) Processing Set

Rx Only
Caution: US Federal law restricts this device to sale by or on the order of a licensed healthcare practitioner

March 10, 2016

INTENDED USE

The INTERCEPT Blood System for platelets is intended to be used for ex vivo preparation of pathogen-reduced Amicus apheresis platelet components suspended in 65% PAS-3/35% plasma, and Trima apheresis platelet components suspended in 100% plasma in order to reduce the risk of transfusion-transmitted infection (TTI), including sepsis, and to potentially reduce the risk of transfusion-associated graft versus host disease (TA-GVHD).

DEVICE DESCRIPTION

The INTERCEPT Blood System for platelets is intended to be used for ex vivo preparation of pathogen-reduced Amicus apheresis platelet components suspended in 65% PAS-3/35% plasma, and Trima apheresis platelet components suspended in 100% plasma in order to reduce the risk of transfusion-transmitted infection (TTI), including sepsis, and to potentially reduce the risk of transfusion-associated graft versus host disease (TA-GVHD).

INTENDED USE

The INTERCEPT Blood System for platelets is intended to be used for ex vivo preparation of pathogen-reduced Amicus apheresis platelet components suspended in 65% PAS-3/35% plasma, and Trima apheresis platelet components suspended in 100% plasma in order to reduce the risk of transfusion-transmitted infection (TTI), including sepsis, and to potentially reduce the risk of transfusion-associated graft versus host disease (TA-GVHD).

DEVICE DESCRIPTION

The INTERCEPT Blood System for platelets, DS Processing Set, contains a sterile, non-pyrogenic, single-use, integrated, fluid path platelet processing set (INT2510) comprised of four key components (See Table 1) and an ultraviolet (UVA) illumination device (INT100) for the ex vivo preparation and storage of pathogen reduced apheresis platelet components. The INT100 is a microprocessor controlled device designed to deliver a controlled amount of UVA light, wavelength 320 to 400 nm, to up to two illumination containers simultaneously. The device is programmed to be able to control, deliver, record and store intensity and duration of light dose for each cycle.

</table>

The operating principle for the INTERCEPT Blood System for platelets is illustrated below (Figure 1). Platelets collected by apheresis in a container are sterile connected to the Platelet DS Processing Set [INT2510]. The platelets flow through the amotosalen container into the illumination container. The illumination container is placed into the INT100 illumination device for UVA treatment while being mixed with horizontal agitation. Inactivation of potential pathogen or leukocyte contaminants in platelet components is achieved through a photochemical treatment process. Amotosalen (S-59, psoralen derivative), a chemical capable of binding to nucleic acids is added to platelets. UVA illumination (320 – 400 nm wavelengths) of amotosalen-treated platelet components induces covalent cross-linking of any nucleic acids to which amotosalen is bound; thereby, preventing further replication. Treated platelets are then transferred to the CAD container to reduce the levels of residual amotosalen and free photoproduts. Finally, the platelet components are transferred through the in-line
filter to the storage container for use or storage at 20-24°C with continuous agitation for up to 5 days from the time of collection.

**Figure 1** INTERCEPT Blood System for Platelets and Treatment Process

Device Performance

The INTERCEPT Blood System inactivates a broad spectrum of enveloped and non-enveloped viruses, Gram-positive and Gram-negative bacteria, spirochetes, parasites and leukocytes. There is no pathogen inactivation process that has been shown to eliminate all pathogens. Certain non-enveloped viruses (e.g., HAV, HEV, B19 and poliovirus) and *Bacillus cereus* spores have demonstrated resistance to the INTERCEPT process.

\( \text{c} \) Study in progress

The INTERCEPT process for platelets reduces a broad spectrum of bacteria by > 4 \( \text{Log}_{10} \) (Table 4) to lower the risk of microbial contamination of blood components.\textsuperscript{21} Bacterial spores are resistant to inactivation by the INTERCEPT Blood System for platelets.

Contaminating T cell activity is reduced by the INTERCEPT treatment, potentially lowering the risk of transfusion-associated graft versus host disease (TA-GVHD).\textsuperscript{22-27} Using a limiting dilution assay (LDA), platelets processed with the INTERCEPT Blood System exhibited a 4 \( \text{Log}_{10} \) reduction of viable T-cells. Using a DNA modification assay, platelets processed with the INTERCEPT Blood System demonstrated an average of one amotosalen adduct every 83 base pairs in leukocytes.

\textit{In vitro Characterization of Platelet Components Processed with the INTERCEPT Blood System.}

\textit{In vitro} platelet function characteristics were evaluated in prospective, randomized, paired, controlled, \textit{in vitro} studies in healthy subjects of INTERCEPT apheresis platelet components compared to unprocessed (control) platelet components. Each study subject donated a single- or double-apheresis platelet component, during each of the two donation periods. Components from the platelet donations were randomized to produce INTERCEPT processed platelet components or control platelet components. \textit{In vitro} platelet function of the platelet components was evaluated on day 5 after apheresis donation. The physical and metabolic characteristics for evaluation included: component volume platelet count, platelet volume (MPV), pH\textsubscript{22°C}, pO\textsubscript{2}, pCO\textsubscript{2}, HCO\textsubscript{3}, morphology, supernatant LDH activity, P-selectin, total ATP, extent of shape change, hypotonic shock response, supernatant glucose, and supernatant lactate. Trima platelets suspended in 100% plasma were evaluated further.

1. \textit{Storage in 65\% PAS-3/35\% Plasma:}

63 single-dose and double-dose Amicus platelet collections containing \( 2.9 - 8.0 \times 10^{11} \) platelets in PAS-3 treated with the INTERCEPT Blood System for platelets and stored for 5 days retained presumptively therapeutically effective platelet doses (mean of \( 3.7 \times 10^{11} \) platelets and lower bound of the 95\% confidence interval (CI) for the proportion of INTERCEPT processed platelet components retaining \( >3.0 \times 10^{11} \) platelets was 78.3\%) with an average dose recovery after INTERCEPT treatment of 91.19\% (95\% CI: 89.7\%-92.7\%), and with retention of adequate \textit{in vitro} metabolic and functional properties (Table 6).

The proportion of platelet units of the DS set containing a platelet dose ≥ 3.0 x 10^{11} platelets on Day 5 was 89.0% (195 out of 219), and the lower bound of the 95% CI for the proportion of units containing a platelet dose ≥ 3.0 x 10^{11} platelets was 84.9% (Table 8).

The combined overall results of the two in-vitro studies described above show that INTERCEPT Trima platelets suspended in 100% plasma retain presumptively therapeutically effective mean platelet doses, with retention of adequate in vitro metabolic and functional properties.
CONTRAINDICATIONS

- Contraindicated for preparation of platelet components intended for patients with a history of hypersensitivity reaction to amotosalen or other psoralens.

- Contraindicated for preparation of platelet components intended for neonatal patients treated with phototherapy devices that emit a peak energy wavelength less than 425 nm, or have a lower bound of the emission bandwidth <375 nm, due to the potential for erythema resulting from interaction between ultraviolet light and amotosalen.

Note: Information about these contraindications needs to be included in the labeling provided with transfusable platelets prepared using the INTERCEPT Blood System for platelets.

WARNINGS AND PRECAUTIONS

- Only INTERCEPT Processing Sets for platelets are approved for use with the INTERCEPT Blood System. Use only the INTERCEPT INT100 Illuminator for UVA illumination of amotosalen-treated platelet components. No other source of UVA light may be used. Please refer to the Operator’s Manual for the INT100 Illuminator. Discard any platelet components not exposed to the complete INT100 illumination process.

- Tubing components and container ports of the INTERCEPT Blood System contain polyvinyl chloride (PVC). Di(2-ethylhexyl)phthalate (DEHP) is known to be released from PVC medical devices, and increased leaching can occur with extended storage or increased surface area contact. Blood components will be in contact with PVC for a brief period of time (approx. 15 minutes) during processing. The risks associated with DEHP released into the blood components must be weighed against the benefits of therapeutic transfusion.

- Pulmonary events: Acute Respiratory Distress Syndrome (ARDS)

INTERCEPT processed platelets may cause the following adverse reaction: Acute Respiratory Distress Syndrome (ARDS)

An increased incidence of ARDS was reported in a randomized trial for recipients of INTERCEPT processed platelets, 5/318 (1.6%), compared to recipients of conventional platelet components (0/327).28 Monitor patients for signs and symptoms of ARDS.

Note: Information about these Warnings and Precautions needs to be included in the labeling provided with transfusable platelets prepared using the INTERCEPT Blood System for Platelets.
INSTRUCTIONS FOR USE

Initial Setup

Equipment Provided: One (1) INT2510 Dual Storage Processing Set
Equipment Available Separately: INTERCEPT INT100 Illuminator
Equipment Required But Not Provided: Sterile Connecting Device (SCD), Tube Sealer, Flatbed Agitator, Manual Tube Clamp (e.g., Hemostat)

- INTERCEPT Processing Sets for platelets are for single use only. Do not reuse sets or components of sets.

- This process is designed to be a functionally closed system. Treatment with INTERCEPT Blood System does not replace applicable standards for processing in open and closed systems.

Blood Collection

Leukocyte reduced platelets collected by apheresis are used. Refer to Table 9 for specifications of the platelet products which are used with this processing set.

Platelet Processing

Platelets must be exposed to UVA light within 24 hours after collection.

Refer to Figure 2 for labeling and identification of set components.
I. Amotosalen Addition

NOTE: Amotosalen in contact with skin may result in photosensitization in the presence of ultraviolet light. If skin exposure occurs, flush exposed skin with water.

1. Remove set from package. Unwrap only illumination container (1) from organizer.
2. Weld tubing from platelet collection container to amotosalen container (A) tubing using SCD.
3. Label storage container (3) using appropriate donation identification.
4. Hang platelet collection container and break cannula (C) below amotosalen container (A) to let amotosalen flow into illumination container (1); visually verify amotosalen is present.
5. Break cannula (B) above amotosalen container (A) to let platelets flow through amotosalen container (A) into illumination container (1).
6. Ensure the platelets drain completely from initial platelet collection container into illumination container (1) by expressing air from the illumination container (1) into amotosalen container (A).
7. When air is removed and platelets have fully drained back through tubing into illumination container (1), manually clamp tubing above illumination container. Mix illumination container thoroughly by gentle agitation to ensure complete mixing of amotosalen and platelets (Figure 3).
8. Open manual tube clamp and express a small amount of platelet and amotosalen mixture into tubing, filling about 1.5 inches of tubing. Close manual clamp.
9. Seal tubing between illumination container (①) and amotosalen container (②) within the 1.5 inches of tubing (See Figure 4).

10. Remove and discard empty platelet collection container, amotosalen container (②) and excess tubing.

II. Illumination

Refer to INT100 Illuminator Operator’s Manual for detailed instructions.

NOTE: The inactivation process requires unimpeded light transmission through tray and illumination container. The illumination container and tubing must be within the large compartment of the illuminator tray. Tray must be clean and free from labels or other material (see Figure 5). Illumination container should lay flat in order to ensure complete illumination.

NOTE: During illumination, tubing must be held within large compartment of illumination tray (see below).
Figure 5  Proper Way to Load Processing Set Into the Illuminator Tray

Correct:  
Tray is clean.

Correct:  
Labels, if present, are located where they will not block exposure to UV light.

Correct:  
Tubing is correct length and is placed completely within the large area of tray to receive UV exposure.

Incorrect:  
Air must be expressed prior to treatment.

Incorrect:  
Labels on the illumination container may impede exposure to UV light.

Incorrect:  
Tubing is too long and protrudes outside of the large compartment of illumination tray.
III. Agitation with Compound Adsorption Device (CAD)

**Do not fold or bend CAD.**

1. Unwrap set from organizer.
2. Hang platelets in illumination container (1), break cannula (2) and allow platelets to flow into CAD container (3).
3. Express air from CAD container (2) into illumination container (1). Do not fold or bend CAD.
4. Seal tubing close to inlet port of CAD container (2).
5. Remove and discard empty illumination container (1) and excess tubing.
6. Place CAD container (2) flat on flatbed agitator with attached storage containers for 6-16 hours for Amicus platelets in PAS-3 or 12-24 hours for Trima platelets in 100% plasma. Agitation rate must be at least 60 RPM. Do not stop the process before the minimum time and do not extend the process beyond the maximum allowable time.
7. Do not fold or place storage container (3), in line filter, or any tubing under CAD container (2) during agitation.

IV. Transfer to Storage Container

1. Remove platelets from agitator and hang platelets in CAD container (2).
2. Expel air from platelet sampling pouch into storage container and close clamps (6).
3. Break cannula (5) at outlet of CAD container (2) and allow platelets to flow into each of the two storage containers (3).
4. Express air from storage containers (3) into CAD container (2) and close clamp above the Y fitting.
5. Redistribute volume between storage containers (3) as needed. Note: Steps 4 and 5 may be performed in the reverse order.
6. Ensure appropriate donor identification is attached to each filled platelet storage container (3).
7. Seal tubing close to the outlet of the Y fitting as needed for each therapeutic dose of platelets.
   - For Amicus platelets in PAS-3: If the input platelet dose to the INTERCEPT process is greater than or equal to $6.1 \times 10^{11}$, the product should be stored in two separate containers.
   - For Trima platelets in 100% plasma:
     - If the input platelet dose to the INTERCEPT process is greater than or equal to $5.3 \times 10^{11}$ but smaller than $7.1 \times 10^{11}$, the product should be stored in two connected containers.
     - If the input platelet dose to the INTERCEPT process is greater than or equal to $7.1 \times 10^{11}$ the product should be stored in two separate containers.
8. Remove and discard empty CAD container (2) and tubing. Place platelets on platelet agitator.

The INTERCEPT treatment process is now complete.

V. Sampling Platelet Product (optional)

1. Mix INTERCEPT treated platelets by gently agitating platelet storage container.
2. Open clamp (6) to platelet sampling pouch and squeeze several times.
3. Allow sampling pouch to fill with platelets. Seal tubing.
4. Remove sample pouch.
5. Transfer sample to appropriate laboratory tube immediately.
STORAGE AND HANDLING

Processing Sets

- Do not use if tamper-evident package has been opened, signs of deterioration are visible, fluid path closures are loose or not intact, cannulae are broken or if there is no fluid in the amotosalen solution container.
- Protect the processing set package and tubing from sharp objects. Discard platelet product if there is a leak in the set during processing.
- Keep processing sets in the light-protective, aluminum foil pouch until time of use. Protect from direct sunlight and strong UVA light source.
- Do not store processing set above 25°C.
- Do not vent.
- Do not freeze.
- Unused processing sets may be stored for up to 20 days at room temperature (18 – 25°C) in the open aluminum foil pouch by folding and securing the open end of the pouch. Record the “Date Opened” and “Use By” date on the foil pouch label in the space provided. The processing sets removed from the aluminum foil pouch must be used within 8 hours.

Platelet Components

- Platelet components processed with the INTERCEPT Blood System must be stored in the platelet storage container provided in the INT2510 processing sets.
- Processed platelet components may be stored at 20-24°C with continuous agitation for up to 5 days from the day of collection.

NONCLINICAL TOXICOLOGY

Nonclinical studies were conducted in mice, rats and dogs to evaluate the potential toxicity of single and repeated exposures to amotosalen, the synthetic psoralen derivative used in the INTERCEPT process to cross-link DNA and RNA. A single, intravenous injection of amotosalen alone resulted in mortality in rats at doses equal to or greater than 100,000-fold the anticipated human clinical exposure from a single transfusion of INTERCEPT processed platelets as compared on a dose per kilogram body weight basis. Lower doses of amotosalen (12,000- or 60,000-fold greater than the anticipated human clinical exposure in dogs and rats, respectively) were not lethal, and resulted in transient clinical signs of toxicity (i.e. piloerection, inactivity, hunched posture and abnormal breathing in rats, and excessive salivation, swelling of the muzzle and eyelids, and non-lethal cardiac arrhythmias in dogs). No target organ toxicities were noted at necropsy.29

Animal experiments with amotosalen provided no indication of an increased toxicological risk for the use of platelets treated using the INTERCEPT Blood System. Repeat-dose toxicity studies in rats and dogs dosed by daily intravenous injection for 7 to 28 days with amotosalen, at doses with at least 30,000- and 10,000-fold, respectively, the anticipated clinical exposure from transfusion of 300 mL of INTERCEPT Blood System-processed platelets showed no evidence of toxicity.29, 30 Transient, minor changes in hematology profiles with no correlating histopathology findings or major organ toxicities were reported in dogs dosed 3 times weekly for 13 weeks with autologous platelets processed with the INTERCEPT Blood System, at a cumulative amotosalen
exposure of approximately 115-fold the anticipated clinical exposure following a single transfusion of 300 mL of INTERCEPT processed platelets.

Amotosalen was rapidly eliminated in mice and rats with an initial plasma t$_{1/2}$ of less than 1 hour. There was no evidence of amotosalen accumulation after repeated exposures over periods as long as 13 weeks. The primary route of excretion of amotosalen and its photoproducts was fecal.$^{29}$

No effects on fertility parameters were noted in male or female rats dosed with amotosalen. In studies evaluating the effects of amotosalen dosing of pregnant rats or rabbits on embryo-fetal or peri-postnatal development in pregnant rats and rabbits, and in one study dosing neonatal rats with amotosalen, there was no evidence of teratogenicity, or other reproductive or developmental toxicities.$^{31}$

No evidence of genotoxicity or mutagenicity was observed in the in vitro or in vivo mutagenicity studies of amotosalen. In transgenic mice heterozygous for the p53 tumor suppressor gene, there was no evidence of carcinogenicity after repeated three times weekly dosing with amotosalen for 6 months at cumulative weekly doses approximately 1200 times the daily human exposure from a single 300 mL transfusion of INTERCEPT Blood System-treated platelets.$^{32}$

**CLINICAL STUDIES**

The safety and effectiveness of INTERCEPT processed platelets were investigated in 10 controlled clinical studies.$^{33-42}$ A total of 844 study subjects received INTERCEPT processed platelets in these clinical studies.

Three trials were conducted in healthy volunteers to measure the viability of INTERCEPT processed platelets and the clearance of residual amotosalen.$^{33,34}$ Three studies utilized small doses (15-20 mL) of radiolabelled platelets; and in one study a full therapeutic dose (300 mL) was administered. All platelet components (PCs) were apheresis collections.

The primary endpoint of the three studies with radiolabelled platelets was post-transfusion viability of autologous INTERCEPT processed platelets after 5 days of storage. Autologous platelets from healthy donors prepared with the prototype IBS System (no amotosalen reduction) and stored for 5 days before transfusion demonstrated mean post transfusion recovery 77.8 % of untreated PCs, and mean life span 74.5 % of untreated PCs. Similarly, autologous platelets from healthy donors prepared with the prototype IBS System (with amotosalen reduction) and stored for 5 days before transfusion demonstrated mean post transfusion recovery 84.5 % of untreated PCs and life span 80 % of untreated PCs.

The primary endpoint of the full dose transfusion of INTERCEPT processed platelets was clearance of residual amotosalen. Peak post transfusion amotosalen levels were < 1 ng/ml with clearance kinetics of residual amotosalen median terminal ($T_{50} = 6.5$ hr) with acceptable tolerability after rapid transfusion of a therapeutic platelet dose.$^{34}$

No clinically relevant adverse events were observed in healthy subjects exposed to small volumes of autologous radiolabeled platelets or after transfusion of 300 mL of autologous INTERCEPT treated platelet components.

A randomized, controlled, double blind, parallel-group study to compare the therapeutic efficacy and safety of INTERCEPT processed apheresis platelet components to conventional apheresis platelet components using a non-inferiority design was conducted in patients requiring 1 or more platelet transfusions to support hypoplastic
thrombocytopenia. The study was designed to assess the proportion of patients with Grade 2 bleeding during up

to 28 days of platelet transfusion support. A total of 645 patients (318 Test, 327 Reference) received a total of

4719 platelet transfusions (2678 Test, 2041 Reference). There were 186/318 (58.5%) patients in the Test group

and 188/327 (57.5%) patients in the Reference group with Grade 2 bleeding. The test result met the efficacy

success criteria of the non-inferiority margin of 12.5%. Differences in mean number of transfusions, average

interval between transfusions, rates of refractoriness, mean days with Grade 2 bleeding and mean count increment

and corrected count increment at 1 and 24 hours were all statistically significantly different favoring the control

group. The targeted platelet transfusion dose was 3.7x10¹¹. Sixty percent of the subjects in the INTERCEPT

processed platelet group received a platelet dose of less than 3x10¹¹ compared to 36% in the control group.

Additionally, subjects in the INTERCEPT processed platelet group received off-protocol transfusions (32 vs.

15%) more often than the control group because of protocol violations. In order to assess whether the platelet
dose could have impacted all these efficacy endpoint outcomes, a post-hoc analyses on three different subsets of

subjects: subjects who received transfusions dose of platelets ≥3x10¹¹, subjects who received off-protocol

transfusions, and subsets who received transfusions dose of platelets ≥3x10¹¹ without any off-protocol

transfusions was conducted. In all the three subsets, a statistically significant difference was no longer seen in

mean days with Grade 2 bleeding and in the mean number of platelet transfusions. Adjusting the platelet dose per

unit to ≥3x10¹¹ may overcome the differences of these outcomes seen in the original study analysis.

There were no differences between treatment groups in the frequencies of Grade 3 and Grade 4 adverse events,

serious adverse events, or mortality. Statistically significant differences for increased incidence of four adverse

events of Grade 3 and Grade 4 severity were observed among recipients of INTERCEPT processed platelets.

These included: pneumonitis not otherwise specified (5 versus 0); ARDS (5 versus 0); hypocalcemia

(21 versus 8); and syncope (6 versus 0). A subsequent blinded, retrospective analysis of patients with clinically

significant pulmonary adverse events (n = 148) demonstrated no significant increase in incidence of acute lung

injury (ALI), including ARDS. However a trend of increased ARDS in the patients receiving INTERCEPT

processed platelets remained. The causality of these events remains uncertain and an increased risk of ARDS with

the INTERCEPT processed platelets cannot be ruled out.

Another randomized, double-blind, controlled, parallel-group trial was conducted to evaluate the efficacy and

safety of apheresis INTERCEPT processed platelets prepared with the commercial INTERCEPT system

compared to conventional apheresis PCs. A total of 43 adult hematology-oncology patients with hypoplastic

thrombocytopenia (22 Test, 21 Reference) were enrolled at 3 study centers. INTERCEPT treatment was used in

place of gamma irradiation for 93% of INTERCEPT PCs for prevention of TA-GVHD. A total of 218 platelet

components were transfused (103 Test and 115 Reference). The primary endpoint was the 1-hour platelet count

increment. There was no excess treatment related morbidity reported among patients supported with

INTERCEPT processed platelet components.

A single-arm, open label safety study of 560 INTERCEPT processed platelet transfusions in 51 adult patients with

malignant hematology-oncology disorders, including HSCT was conducted to assess the frequency of acute

transfusion reactions. Platelet concentrates were prepared from either apheresis collections or whole blood

derived buffy coat platelets, treated with INTERCEPT in place of gamma irradiation, and stored up to 5 days

prior to transfusion. The frequency of acute transfusion reactions was 1.6%. This study was small in size and

uncontrolled therefore the rate of acute transfusion reactions cannot be compared with that for conventional

platelets.

A single-arm, open label observational study to assess acute transfusion reactions using apheresis “double unit”
collections (5-6 x 10¹¹) without gamma irradiation and stored up to 5 days was conducted in 46 adult hematology
patients with malignant disorders, including HSCT. A total of 551 INTERCEPT processed platelet transfusions were administered in a Swiss Red Cross blood center. The frequency of acute transfusion reactions was 2%. This study was small in size and uncontrolled therefore the rate of acute transfusion reactions cannot be compared with that for conventional platelets.

**Post-Marketing Studies**

Safety data were obtained from three hemovigilance (HV) programs in routine use without patient selection: the Cerus hemovigilance program and the regulatory surveillance programs in France and in Switzerland.

The populations monitored in the Cerus hemovigilance studies included 4,067 patients, where 59 patients were under the age of 1 year and 185 patients were 1-18 years of age. 51% of the patients enrolled in these studies were hematology-oncology patients, of which 12% were HSCT patients. Adverse events within 24 hours and serious adverse events within 7 days of platelet transfusion were reported. The frequencies of adverse events attributed to INTERCEPT processed platelet transfusions were not increased compared to conventional platelet transfusions reported in European regulatory hemovigilance programs.

**Clinical Experience with Transfusion of INTERCEPT Platelets Suspended in 100% Plasma**

Cerus conducted an analysis of the CLI-HV 00079 study to support the current PMA supplement for the use of the INTERCEPT Blood System for platelets suspended in 100% plasma. The final report (CLI-HV 00079-2) included data for 502 INTERCEPT platelet components suspended in 100% plasma. This study was an observational safety study to detect adverse events (AEs) that if imputed as related to the transfusion were classified as transfusion reactions (TR). Adverse events related to failure of hemostasis in thrombocytopenic patients could be reported in this study. Five hundred and two INTERCEPT platelet components were administered to 169 patients. All patients received INTERCEPT platelet components for hematology-oncology related diseases including HSCT (99.4%) or surgery (0.6%).

AEs were observed following transfusion of 5 INTERCEPT components (1.0%) in 4 patients (2.4%). No AEs were classified as “serious” (SAE) following transfusion of INTERCEPT PC. No adverse events related to bleeding or hemostatic failure were reported. The 4 patients who suffered an AE experienced chills (2 patients, 1.2%), pain (1 patient, 0.6%), pyrexia (3 patients, 1.8%) and rash (1 patient, 0.6%). Based on a clinical causality assessment, these AEs were classified as febrile non-hemolytic transfusion reactions with expected signs and symptoms (pyrexia and rash), and HLA antibody associated with lower back pain. The patients recovered from these adverse events on the day of transfusion, no transfusions were interrupted due to any AE or transfusion reaction, and no patients died during the study. The types of AEs were representative of the types of events experienced by patients with transfusion-dependent thrombocytopenia and were consistent with the types of events commonly experienced by patients following transfusion of conventional platelet components according to published data and national hemovigilance programs. No transfusion related acute lung injury (TRALI), transfusion-related sepsis (TRS), or transfusion-associated graft versus host disease (TA-GVHD) were reported. The frequencies of these AEs were comparable to historical data for conventional PCs 100% plasma. Transfusions of INTERCEPT PCs were well tolerated during this observational study, and the study provides further clinical data to support the use of the INTERCEPT Blood System with platelets suspended in 100% plasma.
ANSM and Swissmedic Active HV Programs (France and Switzerland)

Since 2009, INTERCEPT processed platelets suspended in PAS-3 (InterSol™) have been monitored in comparison to other types of platelet concentrates (suspended in PAS-3 or in 100% plasma) transfused in France and Switzerland through a national hemovigilance program. In Switzerland, INTERCEPT processed platelets were phased into routine use during 2011, accounting for approximately 80% of all platelet concentrates transfused that year, and 100% of platelets produced thereafter. No septic transfusion reactions due to bacterial contamination of platelets were observed after the introduction of INTERCEPT processed platelets in France or Switzerland. The number of TRALI reported to the HV systems during the years 2009-2013 is small, and the TRALI rates were similar in both groups. There were 6/187,142 TRALI cases per INTERCEPT processed platelet transfusions, for a TRALI rate of 0.33 per 10,000 platelet transfusion, compared to 37/1,109,135 TRALI cases per conventional platelet transfusions, for a rate of 0.32 per 10,000 platelet transfusions. Limitations of the hemovigilance system include data collection that was limited to only transfusion associated AEs (TRALI, TACO, TAD, etc.) as assessed by the reporter.
