2 (8:30 a.m.)

3 **Call to Order**

4 **Introduction of Committee**

5 DR. BADEN: Good morning. It is now 8:30.

6 I would first like to remind everyone to please
7 silence your cell phones, smartphones, and any
8 other devices, if you have not done so already. I
9 would also like to identify the FDA press contact,
10 Theresa Eisenman. If you are present, please stand
11 in the back.

12 My name is Lindsey Baden. I'm the
13 chairperson of the Antimicrobial Drug Advisory
14 Committee. I will now call this meeting of the
15 Antimicrobial Drug Advisory Committee to order.
16 We'll start by going around the table and
17 introducing ourselves. Let's start on the right.

18 DR. BERNSTEIN: Barry Bernstein, vice
19 president, infectious disease development, AbbVie,
20 retired, the industry representative.

21 DR. SURAWICZ: Chris Surawicz, University of
22 Washington. I'm a gastroenterologist.

1 DR. GOETZ: Matthew Goetz, infectious
2 diseases at the VA Greater Los Angeles and UCLA.

3 DR. HILTON: Joan Hilton, professor of
4 biostatistics, UCSF.

5 DR. MOORE: Tom Moore, infectious disease in
6 Wichita, Kansas at the University of Kansas.

7 DR. GEA-BANACLOCHE: Juan Gea-Banacloche,
8 infectious diseases, NCI.

9 MS. THOMAS: Jeanine Thomas, Founder,
10 President, MRSA Survivors Network.

11 DR. HONEGGER: Jonathan Honegger, pediatric
12 infectious disease, Ohio State University.

13 DR. SCHAEENMAN: And I'm Joanna Schaeenman,
14 infectious diseases, David Geffen School of
15 Medicine at UCLA.

16 DR. WEINA: Pete Weina. I'm infectious
17 disease and director of research programs at Walter
18 Reed National Military Medical Center.

19 DR. GRIPSHOVER: Hi. I'm Barbara Gripshover
20 from University Hospitals of Cleveland, Case
21 Western Reserve, infectious disease.

22 DR. BADEN: Lindsey Baden, infectious

1 diseases, Brigham and Women's, Dana-Farber, and
2 Harvard Medical School.

3 DR. TESH: Lauren Tesh, designated federal
4 officer for AMDAC.

5 DR. GREEN: Michael Green, pediatric
6 infectious diseases, Children's Hospital Pittsburgh
7 and the University of Pittsburgh.

8 DR. DASKALAKIS: Demetre Daskalakis, adult
9 infectious diseases. I work for New York State
10 Department of Health and Mental Hygiene.

11 DR. ANDREWS: Ellen Andrews from the
12 Connecticut Health Policy Project, and I'm the
13 consumer representative.

14 DR. CORBETT: Amanda Corbett. I'm a
15 clinical associate professor at the University of
16 North Carolina, Eshelman School of Pharmacy.

17 DR. FOLLMANN: I'm Dean Follmann, head of
18 biostatistics at the National Institute of Allergy
19 and Infectious Diseases.

20 DR. DIXON: Cheryl Dixon, statistics
21 reviewer, FDA.

22 DR. HIRUY: Hiwot Hiruy, clinical safety

1 reviewer.

2 DR. MISHRA: Shrimant Mishra, clinical
3 efficacy reviewer.

4 DR. IARIKOV: Dmitri Iarikov, clinical team
5 leader.

6 DR. NAMBIAR: Good morning. Sumathi
7 Nambiar, director, Division of Anti-Infective
8 Products, CDER, FDA.

9 DR. COX: Ed Cox, director of the Office of
10 Antimicrobial Products, CDER, FDA. Good morning.

11 DR. BADEN: For topics such as those being
12 discussed at today's meeting, there are often a
13 variety of opinions, some of which are quite
14 strongly held. Our goal is that today's meeting
15 will be a fair and open forum for discussion of
16 these issues, and that individuals can express
17 their views without interruption. Thus, a gentle
18 reminder, individuals will be allowed to speak into
19 the record only if recognized by the chairperson.
20 We look forward to a productive meeting.

21 In the spirit of the Federal Advisory
22 Committee Act and the Government in the Sunshine

1 Act, we ask that the advisory committee members
2 take care that their conversations about the topic
3 at hand take place in the open forum of the
4 meeting.

5 We are aware that members of the media are
6 anxious to speak with the FDA about these
7 proceedings. However, FDA will refrain from
8 discussing the details of this meeting with the
9 media until its conclusion. Also, the committee is
10 reminded to please refrain from discussing the
11 meeting topic during breaks or lunch. Thank you
12 very much.

13 Now I'll pass it to Dr. Lauren Tesh, who
14 will read the Conflict of Interest Statement.

15 **Conflict of Interest Statement**

16 DR. TESH: Good morning. The Food and Drug
17 Administration is convening today's meeting of the
18 Antimicrobial Drugs Advisory Committee under the
19 authority of the Federal Advisory Committee Act of
20 1972. With the exception of the industry
21 representative, all members and temporary voting
22 members of the committee are special government

1 employees or regular federal employees from other
2 agencies and are subject to federal conflict of
3 interest laws and regulations.

4 The following information on the status of
5 the committee's compliance with federal ethics and
6 conflict of interest laws, covered by, but not
7 limited to, those found at 18 U.S.C., Section 208,
8 is being provided to participants in today's
9 meeting and to the public.

10 FDA has determined that members and
11 temporary voting members of the committee are in
12 compliance with federal ethics and conflict of
13 interest laws. Under 18 U.S.C., Section 208,
14 Congress has authorized FDA to grant waivers to
15 special government employees and regular federal
16 employees who have potential financial conflicts
17 when it is determined that the agency's need for a
18 special government employee's services outweighs
19 his or her potential financial conflict of
20 interest, or when the interest of a regular federal
21 employee is not so substantial as to be deemed
22 likely to affect the integrity of the services,

1 which the government may expect from the employee.

2 Related to the discussion of today's
3 meeting, members and temporary voting members of
4 the committee have been screened for potential
5 financial conflicts of interest of their own, as
6 well as those imputed to them, including those of
7 their spouses, minor children, and for purposes of
8 18 U.S.C., Section 208, their employers. These
9 interests may include investments, consulting,
10 expert witness testimony, contracts, grants,
11 CRADAs, teaching, speaking, writing, patents and
12 royalties and primary employment.

13 Today's agenda involves a discussion of
14 biologics license application 761046, bezlotoxumab
15 injection, submitted by Merck Sharpe & Dohme Corp.,
16 for the proposed indication of prevention of
17 Clostridium difficile infection recurrence. This
18 is a particular matters meeting during which
19 specific matters related to Merck Sharpe & Dohme's
20 bezlotoxumab will be discussed.

21 Based on the agenda for today's meeting, and
22 all financial interests reported by the committee

1 members and temporary voting members, no conflict
2 of interest waivers have been issued in connection
3 with this meeting. To ensure transparency, we
4 encourage all standing committee members and
5 temporary voting members to disclose any public
6 statements that they have made concerning the
7 product at issue.

8 With respect to FDA's invited industry
9 representative, we would like to disclose that Dr.
10 Barry Bernstein is participating in this meeting as
11 a non-voting industry representative, acting on
12 behalf of regulated industry. Dr. Bernstein's role
13 at this meeting is to represent industry in
14 general, and not any particular company. Dr.
15 Bernstein is employed by AbbVie.

16 We would like to remind members and
17 temporary voting members that if the discussions
18 involve any other products or firms not already on
19 the agenda for which an FDA participant has a
20 personal or financial imputed interest, the
21 participants need to exclude themselves from such
22 involvement, and their exclusion will be noted for

1 the record. FDA encourages all other participants
2 to advise the committee of any financial
3 relationships that they may have with the firm at
4 issue. Thank you.

5 DR. BADEN: We will now proceed with
6 Dr. Nambiar's introductory remarks.

7 **FDA Introductory Remarks - Sumathi Nambiar**

8 DR. NAMBIAR: Thank you, Dr. Baden. Good
9 morning, everybody. Welcome to today's meeting of
10 the Antimicrobial Drugs Advisory Committee to
11 discuss the biologics license application 761046
12 bezlotoxumab injection.

13 The applicant, as you've heard, is Merck
14 Sharpe and Dohme Corp. The proposed indication is
15 prevention of Clostridium difficile infection
16 recurrence in patients 18 years of age and older.
17 The proposed dose is a single dose of 10 milligram
18 per kilogram administered intravenously over 60
19 minutes. The application was granted priority
20 review. There are no approved therapies for
21 prevention of C. diff infection recurrence.

22 Bezlotoxumab is a fully human monoclonal

1 IgG1 kappa antibody that binds to the C. difficile
2 toxin B. The development program was initially
3 focused on the combination of an antitoxin A
4 antibody, actoxumab, and antitoxin B antibody,
5 bezlotoxumab.

6 The applicant has conducted two phase 2
7 trials, Study P017, P018, and two Phase III trials,
8 Studies P001 and P002. In these studies,
9 bezlotoxumab was administered in combination to the
10 standard of care therapy. The duration of standard
11 of care therapy prior to receipt the bezlotoxumab
12 infusion varied.

13 The first phase 2 trial compared antitoxin A
14 antibody to placebo. This trial was terminated
15 early as emerging nonclinical data suggested that
16 the combination of antibodies was more effective.

17 The second phase 2 trial compared antitoxin
18 A, actoxumab, plus bezlotoxumab, antitoxin B, to
19 placebo. Of the 200 patients, 101 were randomized
20 to the antibody arm and 99 to the placebo arm.

21 The initial cure rates in the antibody arm
22 was 79 percent compared to 76 percent in the

1 placebo arm, and recurrent rates in the antibody
2 arm was 7 percent compared to 25 percent in the
3 placebo arm. There was no phase 2 trial that
4 evaluated bezlotoxumab alone.

5 The first phase 3 trial, trial P001, was a
6 4-arm factorial trial design with 1 to 1 to 1 to 1
7 randomization antitoxin A, antitoxin B, the
8 combination, and placebo. The placebo was normal
9 saline. And this design was used to assess the
10 contribution of the individual components
11 consistent with 21 C.F.R. 300.50.

12 In December 2010, a special protocol
13 agreement was reached on the design and endpoints
14 for this trial. The primary endpoint for this
15 trial was recurrence of C. diff infection, and this
16 trial was conducted from 2011 to December 2014.

17 This trial included an interim analysis that
18 allowed for halting enrollment in one or both of
19 the individual antibody arms if there was
20 sufficient evidence of superiority of the
21 combination over the individual antibody arms.

22 After 235 patients received anti A,

1 enrollment in this arm was stopped due to safety
2 concerns relative to placebo and low efficacy
3 compared to the combination arm.

4 The second phase 3 trial, P002, was a 3-arm
5 trial, bezlotoxumab, actoxumab plus bezlotoxumab,
6 and placebo. This protocol was not submitted for a
7 special protocol assessment. Upon review of this
8 protocol, we recommended that the primary endpoint
9 be changed to global cure, and this was to be
10 defined as a patient being cured and having no
11 recurrence.

12 The two main concerns we had with the
13 proposed recurrence endpoint were that when one
14 calculates CDI recurrence, subjects who failed
15 initial treatment would be counted as not having a
16 recurrence. And secondly, if there was any
17 imbalance between the treatment arms for the
18 clinical cure rate of the initial episode, the
19 assessment of recurrence rate could be confounded.

20 The applicant preferred to retain CDI
21 recurrence as the primary endpoint and global cure
22 as a key secondary endpoint in both trials. At

1 that time, we noted that if the monoclonal antibody
2 arm had a lower initial cure rate than the placebo
3 arm, interpretation of the recurrence endpoint
4 would be difficult.

5 We also did not agree with the proposal to
6 evaluate global cure by analyzing pooled data from
7 the two phase 3 trials and noted that assessment of
8 the global cure endpoint would be based on the
9 analysis from each individual trial. This trial
10 was conducted from February 2012 to May 2015.

11 So for today's discussion, the key topic
12 areas from an efficacy standpoint are as follows.
13 There are differences in the assessment of the
14 primary endpoint between the applicant and the
15 agency. There are differences in the clinical
16 outcomes between the two phase 3 trials. And there
17 are also differences in the approach to analyses
18 conducted between the applicant and the FDA.

19 From a safety standpoint, there are no major
20 differences in the assessment between the applicant
21 and the FDA. There'll be some discussion about a
22 higher frequency of adverse reactions seen in

1 patients with baseline congestive heart failure and
2 who were treated with bezlotoxumab.

3 So we'll hear presentations by the
4 applicant. This will be followed by presentations
5 from the FDA. We have two presentations. Dr.
6 Cheryl Dixon will present data on the efficacy
7 assessment. And Dr. Hiwot Hiruy will discuss the
8 safety assessment. After break, we have time for
9 open public hearing, followed by questions for the
10 committee.

11 We have one voting question for the
12 committee, which is, has the applicant provided
13 substantial evidence of the safety and
14 effectiveness of bezlotoxumab for the prevention of
15 C. difficile infection recurrence in patients aged
16 18 years and older? Vote yes or no.

17 If yes, please discuss your rationale and
18 provide any recommendations concerning labeling.
19 If no, please discuss your rationale and what
20 additional studies or analyses are needed. Thank
21 you.

22 DR. BADEN: Thank you, Dr. Nambiar. Both

1 the FDA and the public believe in a transparent
2 process for information gathering and decision
3 making. To ensure such transparency at the
4 advisory committee meeting, FDA believes that it is
5 important to understand the context of an
6 individual's presentation.

7 For this reason, FDA encourages all
8 participants, including the industry's non-employee
9 presenters, to advise the committee of any
10 financial relationships they may have with the firm
11 at issue, such as consulting fees, travel expenses,
12 honoraria, and interests in the industry, including
13 equity interests and those based upon the outcome
14 of the meeting.

15 Likewise, FDA encourages you at the
16 beginning of your presentation to advise the
17 committee if you do not have any such financial
18 relationships. If you choose not to address this
19 issue of financial relationships at the beginning
20 of your presentation, it will not preclude you from
21 speaking. We shall now proceed with the sponsor's
22 presentations. And I think Dr. Staas will be the

1 first presenter.

2 **Sponsor Presentation - Donnette Staas**

3 DR. STAAS: Thank you Dr. Nambiar, and
4 members of the committee, and the FDA. Good
5 morning. I'm Dr. Donnette Staas, and I'm in the
6 Regulatory Affairs group at Merck. It is our
7 pleasure today to bring you the data on
8 bezlotoxumab for the prevention of C. difficile
9 infection recurrence.

10 After this brief introduction, Dr. Dalya
11 Guris will present the clinical efficacy data for
12 bezlotoxumab, and then Dr. Yoshihiko Murata will
13 present the clinical safety data. Professor Mark
14 Wilcox will conclude the presentation with a
15 summary of the benefit-risk profile.

16 Clostridium difficile is a spore-forming,
17 rod-shaped anaerobe bacterium that is easily spread
18 and difficult to eradicate. The bacterium is
19 ubiquitous in the hospital environment, and C.
20 difficile infection, or CDI, has become the leading
21 cause of nosocomial infection. The incidence of
22 community-acquired CDI is also on the rise. There

1 are an estimated 453,000 incident Clostridium
2 difficile infections in the United States in 2011
3 and an additional 83,000 first recurrences of CDI.

4 The associated mortality is high, with an
5 estimated 29,000 CDI-associated deaths that year.
6 In fact, the deaths associated with CDI exceeded
7 those associated with MRSA and multi-drug resistant
8 Gram-negative infections combined.

9 As a result, C. difficile has been declared
10 one of only three urgent antibiotic-resistant
11 threats by the Centers for Disease Control and
12 Prevention, and the disease has aptly earned the
13 pseudonym of deadly diarrhea.

14 As the graph on this slide illustrates,
15 approximately 20 to 35 percent of patients with a
16 primary episode of CDI will go on to have a
17 recurrent episode. The risk of recurrence
18 increases with each subsequent episode, with a
19 recurrence rate of approximately 60 percent after
20 two or more recurrences. CDI recurrence is
21 associated with increased disease severity and
22 higher mortality.

1 Treatment options for both primary and
2 recurrent CDI include oral metronidazole, which is
3 typically limited to mild cases of CDI, intravenous
4 metronidazole, oral vancomycin, and oral
5 fidaxomicin. These treatment options will be
6 referred to as standard of care therapies
7 throughout today's presentation.

8 Antibiotic treatment of CDI does not prevent
9 recurrent disease. Indeed, treatment with
10 vancomycin or metronidazole leads to disruption of
11 the normal gut microbiota, which in turn
12 facilitates CDI recurrence.

13 CDI also recurs at a substantial rate
14 following treatment with fidaxomicin, particularly
15 in those patients infected with ribotype 027. The
16 ribotype 027 strain is one of a group of *C.*
17 *difficile* strains that have been associated with
18 poor clinical outcomes. There are no approved
19 therapies for the prevention of CDI recurrence,
20 thus prevention of CDI recurrence represents an
21 unmet medical need.

22 I will now present an overview of the

1 pathogenesis of the infection. The primary risk
2 factors for developing CDI are, one, the disruption
3 of the normal gut microbiota, which occurs
4 secondary to antibiotic treatment or other factors
5 such as receipt of chemotherapy, and, two, the
6 acquisition of toxigenic *C. difficile*.

7 *C. difficile* expresses two functionally and
8 structurally homologous toxins, toxin A and toxin
9 B. While their relative contribution to disease
10 pathogenesis is an area of ongoing research, the
11 toxins cause the symptoms of CDI by targeting the
12 epithelial cells of the gut, causing damage and
13 inducing inflammation within the intestinal wall.

14 Some patients become asymptomatic carriers
15 and may active as reservoirs for spread of *C.*
16 *difficile*. Others go on to develop *C. difficile*
17 infection with a spectrum of illness ranging from
18 mild diarrhea to extensive diarrhea with abdominal
19 pain, with potential complications including toxic
20 megacolon and colonic perforation, sepsis, and
21 death.

22 Those who develop *C. difficile* infection are

1 treated with standard of care antibiotics.
2 Following treatment, although some patients will be
3 cured with no further complications, approximately
4 20 to 35 percent of patients will go on to
5 experience a recurrent episode. Of note,
6 circulating antitoxin antibodies are protective
7 against primary and recurrent CDI.

8 Monoclonal antibodies directed against the
9 toxins of *C. difficile* represent a novel,
10 non-antibiotic approach to the prevention of CDI
11 recurrence. The premise of this approach is that,
12 as noted on the previous slide, immune responses
13 against toxins A and B are associated with reduced
14 recurrence of CDI.

15 Bezlotoxumab, which will also be referred to
16 as BEZLO throughout this presentation, is a fully
17 human, monoclonal antibody of the IgG1 class.
18 BEZLO binds with high affinity to *C. difficile*
19 toxin B and neutralizes its activity by preventing
20 the binding of toxin to host cells. In clinical
21 trials, BEZLO has been evaluated both alone and in
22 combination with actoxumab, or ACTO, which is the

1 fully human monoclonal antibody targeting toxin A.

2 The phase 3 clinical development program,
3 which is the focus of this morning's presentation,
4 is summarized briefly on this slide. MODIFY I and
5 MODIFY II are the two pivotal phase 3 trials that
6 demonstrated the safety and efficacy of
7 bezlotoxumab for the prevention of CDI recurrence
8 in patients receiving standard of care antibiotic
9 therapy for CDI.

10 The trials were conducted concurrently at
11 over 300 sites across 30 countries in 6 continents.
12 The global phase 3 program is the largest clinical
13 development program conducted to date in assessing
14 outcomes for CDI, randomizing a total of 2,655
15 patients with a primary or recurrent CDI. Both
16 clinical trials are complete.

17 The results of the pivotal phase 3 trials
18 demonstrate that a single dose of bezlotoxumab is
19 highly efficacious in preventing CDI recurrence,
20 significantly decreasing the proportion of subjects
21 with CDI recurrence by 10 percentage points
22 compared to placebo, which translates to a 40

1 percent reduction in relative risk for CDI
2 recurrence.

3 As you can see in this table, the results
4 were consistent across the two trials with a
5 10.1 percentage point absolute difference in CDI
6 recurrence rate between the BEZLO and placebo arms
7 in MODIFY I, and a 9.9 percentage point difference
8 in MODIFY II. Bezlotoxumab is well tolerated with
9 a safety profile similar to placebo. Bezlotoxumab
10 has been shown to have a positive benefit-risk
11 profile.

12 The proposed indication for bezlotoxumab is
13 for the prevention of Clostridium difficile
14 infection recurrence in patients 18 years or older
15 receiving antibiotic therapy for CDI.

16 The recommended dose of bezlotoxumab is 10
17 milligrams per kilogram of patient body weight
18 administered as an intravenous infusion over 60
19 minutes as a single dose. BEZLO may be given at
20 any time during the course of antibiotic therapy
21 for CDI.

22 Regulatory agency guidance was obtained

1 throughout the BEZLO clinical development program.
2 In October 2009, an end-of-phase 2 meeting was held
3 with FDA, during which agreement was reached on the
4 definition and time point for assessment of the
5 primary efficacy endpoint of CDI recurrence for the
6 phase 3 trials.

7 Fast track designation was granted for ACTO
8 plus BEZLO in May 2010 in recognition of the
9 potential of the drug to treat a serious or
10 life-threatening disease or condition and to
11 address an unmet medical need for such a condition.

12 The MODIFY I trial was a subject of a
13 special protocol assessment in 2010 in which
14 agreement was reached on the implementation of a
15 4-arm factorial design to evaluate whether the
16 combination of ACTO plus BEZLO provided additional
17 benefit over the individual monoclonal antibodies
18 in accordance with the combination drug product
19 rule.

20 In August 2012, the FDA recommended that
21 Merck change the primary efficacy endpoint in
22 MODIFY II from CDI recurrence to global cure.

1 Merck considered the CDI recurrence endpoint to be
2 a more appropriate measure to assess efficacy of a
3 therapy that does not treat the incident CDI
4 episode but only prevents CDI recurrence, which is
5 consistent with the mechanism of action of
6 bezlotoxumab.

7 Thus, Merck retained CDI recurrence as the
8 primary endpoint in MODIFY II. Sensitivity
9 analyses were added to assess the impact of
10 clinical cure on CDI recurrence.

11 Following completion of the pivotal phase 3
12 trials, the biologics licensing application was
13 submitted for review in November 2015 with priority
14 review designation granted for the application in
15 January 2016.

16 Merck has several consultants in attendance
17 today and I'd like to acknowledge them. We have
18 Dr. Karen Kelly, professor of medicine at Beth
19 Israel Deaconess Medical Center and Harvard Medical
20 School; Dr. Gary Koch, professor of biostatistics
21 at the University of North Carolina, Chapel Hill;
22 Professor Mark Wilcox, consultant, and head of

1 microbiology and professor of medical microbiology
2 at Leeds Teaching Hospitals and University of Leeds
3 in the United Kingdom and lead on Clostridium
4 difficile at Public Health England; and Dr. Janet
5 Wittes, founder and president of Statistics
6 Collaborative Incorporated.

7 I will now invite Dr. Dalya Guris, who has
8 led the bezlotoxumab clinical development program,
9 to present a detailed discussion of the efficacy
10 data that support the use of BEZLO for the
11 prevention of CDI recurrence. Dalya?

12 **Sponsor Presentation - Dalya Guris**

13 DR. GURIS: Thank you, Donnette. Good
14 morning. My name is Dalya Guris. I'm with Merck
15 Infectious Disease Clinical Research. I will
16 present an overview of bezlotoxumab mechanism of
17 action, bezlotoxumab properties, phase 3 program,
18 and the efficacy results.

19 First, I will begin by illustrating BEZLO's
20 mechanism of action. During the initial episode of
21 CDI, the patient is treated with standard of care
22 antibiotics and also receives a single IV infusion

1 of BEZLO while on antibiotic treatment. The CDI
2 resolves due to antibiotic treatment.

3 However, after initial episode is cured
4 there is a period when the gut microbiota has not
5 yet recovered. And with the outgrowth or newly-
6 acquired C. difficile spores, the patient is at
7 risk for recurrence.

8 The magnified portion of this slide
9 illustrates what occurs at the cellular and
10 molecular level in the gut. The cells in the
11 center represent epithelium of the gut wall.

12 Pre-clinical data have shown that BEZLO
13 enters the gut lumen via paracellular transport,
14 which is facilitated by toxins disruptions of the
15 epithelium. BEZLO binds to toxin B, in turn blocks
16 the binding of toxin to the mucosal cells, and
17 prevents damage and inflammation of the gut wall.

18 BEZLO has a long half-life in circulation,
19 with measurable systemic concentrations throughout
20 the window during which the patient remains at risk
21 for recurrence. During this period, gut microbiota
22 recovers and CDI recurrence is prevented.

1 Bezlotoxumab is a fully human monoclonal
2 antibody specific for an exogenous toxin, toxin B.
3 It is administered as a single dose of 10 milligram
4 per kilogram actual body weight IV infusion over
5 one hour. This dose was selected based on
6 efficacious exposures of ACTO and BEZLO in
7 preclinical studies and was confirmed as
8 efficacious in preventing CDI in phase 2.

9 As it is specific to an exogenous toxin, no
10 off-target activity, including an immune mediator
11 response, is expected. And because it is fully
12 human, potential for immunogenicity is low.

13 Bezlotoxumab is eliminated by protein
14 catabolism with a half-life of 19 days, and it has
15 low drug-drug interaction potential. Bezlotoxumab
16 is not renally or hepatically eliminated, or
17 affected by hepatic drug metabolizing enzymes or
18 transporter proteins.

19 There are no clinically meaningful PK
20 differences between subpopulations such as elderly,
21 patients with hepatic or renal impairment, or by
22 patient weight, and therefore it can be given to a

1 diverse patient population without dose adjustment.

2 The phase 3 program included 2 large,
3 double-blind, randomized clinical trials, which
4 were identical in design except the number of
5 treatment arms included. MODIFY I included
6 4 treatment arms where the patients were randomized
7 to receive either a single infusion of ACTO, BEZLO,
8 ACTO plus BEZLO, or placebo. MODIFY II included 3
9 treatment arms, BEZLO, ACTO plus BEZLO, and
10 placebo.

11 Stratification was identical in MODIFY I and
12 II. Patients were stratified by oral standard of
13 care antibiotics that they were receiving, and
14 their hospitalization status at the time of
15 randomization.

16 Stratification strata for standard of care
17 antibodies were metronidazole, vancomycin, and
18 fidaxomicin, and strata for hospitalization status
19 were inpatient versus outpatient. Hospitalized
20 patients as well as patients from long-term care
21 facilities were included in the inpatient stratum.

22 Four hundred patients per treatment arm was

1 planned in each trial, targeting a total of 1,600
2 patients in MODIFY I and 1200 in MODIFY II.

3 MODIFY I had an adaptive design with an interim
4 analysis. MODIFY I included an interim analysis
5 because, in a small phase 2 study, ACTO alone was
6 found not efficacious in preventing CDI recurrence.

7 ACTO arm was included in the phase 3 program
8 to fulfill FDA's combination product rule, but it
9 was included in only one study and with an interim
10 analysis to allow discontinuation of individual
11 monoclonal antibodies if they were inferior to the
12 combined product.

13 At the interim analysis, ACTO arm was
14 discontinued following the recommendation of the
15 external data monitoring committee based on both
16 efficacy not being achieved and safety findings.

17 MODIFY II had a traditional design without
18 an interim analysis. Adult patients with confirmed
19 CDI were eligible for enrollment. Confirmation was
20 based on both clinical and microbiological
21 criteria, and patients had to be receiving standard
22 of care antibiotic for CDI.

1 The trials had limited exclusion criteria,
2 which allowed a diverse group of CDI patients with
3 multiple underlying comorbidities. Risk factors
4 for CDI recurrence were predefined and patients at
5 risk for CDI recurrence were included. These were
6 elderly patients with multiple previous episodes of
7 CDI, severe CDI, immunocompromised, or infected
8 with hyper-virulent strains associated with poor
9 outcomes.

10 In this slide, you see an outline of the
11 phase 3 trial design. Patients with confirmed CDI
12 were enrolled. To be confirmed, patients had to
13 have diarrhea, which was defined as having 3 or
14 more loose stools in 24 hours, and a positive stool
15 test for toxigenic *C. difficile*. Bristol Stool
16 Chart was used as a method to standardize presence
17 of loose stools using types 5 to 7.

18 Also, patients had to be receiving 10 to
19 14 days of standard of care antibiotic treatment
20 for CDI. Options and dosage for antibiotics were
21 prespecified in the protocols, and choice of
22 antibiotic was left to the treating physician.

1 Standard of care antibiotics were oral
2 metronidazole and oral vancomycin or fidaxomicin
3 with or without IV metronidazole.

4 The antibiotic therapy had to be initiated
5 no later than the day of the infusion. On day 1 of
6 the infusion, patients were randomized equally to
7 one of the treatment arms. Patients could receive
8 study infusion at any time during standard of care
9 antibiotic therapy. Study infusion was given
10 through in-line filter, which is commonly
11 available.

12 During the 85-day follow-up period, patients
13 kept diary to record daily loose stool counts. In
14 the first 2 weeks, patients were contacted every
15 day for loose stool counts and compliance with
16 standard of care medications. Thereafter, patients
17 were contacted twice weekly.

18 If diarrhea returned, stools samples were
19 collected and tested at both local and central
20 laboratory for toxigenic *C. difficile*. Recurrence
21 of diarrhea was assessed throughout the 85-day
22 follow-up period. Primary efficacy endpoint was

1 CDI recurrence after clinical cure of the baseline
2 episode.

3 The primary efficacy endpoint was CDI
4 recurrence. CDI recurrence was defined as a new
5 episode of diarrhea associated with a positive
6 local or central laboratory stool test for
7 toxigenic *C. difficile*, following per protocol
8 definition of clinical cure of the baseline CDI
9 episode.

10 Clinical cure definition included two
11 requirements. The first requirement was to receive
12 a regimen of 14 or fewer days of standard of care
13 antibiotics. The second requirement was the
14 resolution of diarrhea for 2 consecutive days
15 immediately after completion of standard of care
16 antibiotics. Clinical cure was programmatically
17 derived by the sponsor.

18 Efficacy was assessed through 12 weeks and
19 it was assessed in the full analysis set FAS
20 population. Twelve weeks is substantially a longer
21 follow-up period than what has been studied with
22 other therapeutics of CDI.

1 All randomized patients were in the FAS
2 population except those who did not receive an
3 infusion, did not have a positive local stool test
4 for toxigenic C. difficile at study entry, or did
5 not initiate protocol defined standard of care
6 therapy before or on the day of infusion. FAS was
7 the main efficacy population in secondary and
8 exploratory analyses as well.

9 This diagram describes how CDI recurrence
10 rate was calculated. First, in each treatment
11 group, the full analysis set population shown at
12 the top was programmatically assessed by the
13 sponsor for clinical cure of their present CDI
14 episode.

15 Among those who achieved clinical cure,
16 shown in green, patients were evaluated for CDI
17 recurrence, shown in orange. CDI recurrence rate
18 is the proportion of patients with CDI recurrence
19 among the full analysis set population.

20 Patients who did not have clinical cure,
21 shown in black, according the sponsor's
22 programmatic assessment, were not considered to

1 have CDI recurrence given the failure to achieve
2 cure of the baseline episode. They were included
3 in the denominator of the CDI recurrence rate.
4 Later in this presentation, I will show you some
5 alternative definitions that are supportive of the
6 primary endpoint results.

7 Global cure, also known as sustained
8 clinical response, was a secondary endpoint and was
9 defined as having clinical cure of the initial CDI
10 episode and no recurrence in the 12-week follow-up
11 period. As shown in blue in this diagram, global
12 cure rate is the proportion of patients who
13 achieved clinical cure and did not develop CDI
14 recurrence.

15 MODIFY I and II are two independent
16 superiority trials. Each had 95 percent or higher
17 power to detect a clinically relevant absolute
18 difference of 8 percentage points in the rate of
19 CDI recurrence, assuming an underlying placebo rate
20 as low as 16 percent. This would correspond to
21 about a 50 percent reduction in the relative risk
22 of CDI recurrence.

1 Multiplicity strategy controlled the
2 study-wise type 1 error at 0.025, one-sided, for
3 the primary endpoint of CDI recurrence. The
4 prespecified integrated analyses of MODIFY I plus
5 II increased precision to estimate treatment effect
6 of BEZLO on CDI recurrence within important
7 subgroups and on global cure.

8 This slide shows the number of patients
9 randomized and were eligible for safety and
10 efficacy analyses in each treatment group in
11 MODIFY I. A total of 1,452 patients were
12 randomized in MODIFY I.

13 Approximately 400 patients were in each
14 treatment arm, with the exception of the ACTO arm
15 shown in the column far right. Because enrollment
16 in this arm was discontinued at interim analysis,
17 the number of patients randomized was lower.

18 All patients who received a study infusion
19 were evaluated for safety. This population is
20 called all patients as treated, APaT. Few patients
21 were excluded from the efficacy analysis due to not
22 receiving standard of care antibiotic, or not

1 having a confirmed CDI, or being enrolled in a
2 single site from which data could not be verified.

3 Across treatment groups, 95 to 98 percent of
4 all randomized patients were included in the full
5 analysis set population for efficacy analyses. A
6 large proportion of patients completed the 12-week
7 follow-up period across all treatment groups. Main
8 reason for discontinuation was death, as expected
9 from this elderly population with CDI and
10 underlying comorbidities.

11 A total of 1203 patients were enrolled in
12 MODIFY II. Similar to MODIFY I, a high proportion
13 of patients were qualified for safety and efficacy
14 evaluation and completed 12-week follow-up period
15 across all treatment groups.

16 This table shows baseline characteristics of
17 patients by treatment group in MODIFY I and
18 MODIFY II separately. The median age and the
19 proportion of patients by gender, region,
20 hospitalization status and standard of care
21 antibiotics received were comparable between
22 treatment groups in each trial. Median age ranged

1 between 63 and 70 years, and a slightly higher
2 proportion of women were enrolled into the study
3 than men.

4 Nearly half of the patients were from North
5 America in MODIFY I, and in MODIFY II a larger
6 proportion of patients were enrolled from Europe
7 and Asia-Pacific.

8 Proportion of patients from the United
9 States ranged between 44 and 52 percent in the
10 treatment groups in MODIFY I and 34 to 35 percent
11 in MODIFY II. Overall, two-thirds of the patients
12 were inpatients at the time of randomization, and
13 distribution was comparable across the treatment
14 groups.

15 The proportion of patients who received
16 metronidazole or vancomycin as standard of care
17 antibiotic for CDI treatment was similar to each
18 other and across the treatment groups. In each
19 treatment group, approximately 3 to 4 percent of
20 the patients received fidaxomicin, which reflects
21 standard of care for CDI at the time of trials.

22 As I mentioned, there are certain risk

1 factors that are associated with high rates of CDI
2 recurrence. These factors were prespecified in the
3 trials, and patients with these risk factors were
4 included. Overall, the proportion of patients 65
5 years of age or older were comparable between the
6 treatment groups.

7 Nearly one-third of the patients had at
8 least one previous episode of CDI in the past
9 6 months before enrolling in the trials, and the
10 proportion of such patients was comparable across
11 the treatment groups.

12 In addition, 11 to 18 percent of subjects
13 across treatment groups had experienced at least 2
14 episodes of CDI before enrollment.

15 Severity of CDI was assessed at the time of
16 randomization and was defined as having a Zar score
17 of 2 or more. The Zar scale is a method that has
18 been used in clinical studies to assess CDI
19 severity. It takes into account age, body
20 temperature, albumin level, peripheral white blood
21 cell count, presence of endoscopic evidence of
22 pseudomembranous colitis, and treatment in

1 intensive care unit.

2 At the time of randomization, 14 to 21
3 percent of patients had severe CDI across treatment
4 groups. Similarly, a substantial proportion of
5 patients enrolled were immunocompromised, and
6 distribution was comparable across treatment
7 groups.

8 More than 130 distinct *C. difficile* types
9 were identified at baseline. Among the patients
10 with *C. difficile* organism isolated, a large
11 proportion of patients were infected with a hyper
12 virulent strain, including 027 strain. Overall, 76
13 percent of patients had at least one risk factor
14 for CDI recurrence.

15 Now, the efficacy results -- this slide
16 presents the primary efficacy endpoint of CDI
17 recurrence from left to right in MODIFY I,
18 MODIFY II, and the integrated analysis of MODFIY I
19 plus II.

20 Bezlotoxumab was superior to placebo in
21 MODIFY I and MODIFY II and the integrated dataset
22 and significantly reduced CDI recurrence rates

1 compared to placebo, resulting in a relative
2 reduction of CDI recurrence rate by approximately
3 40 percent.

4 Both the CDI recurrence rates and reductions
5 in CDI recurrence were consistent across the two
6 trials. In each of the trials, as well as the
7 integrated data, ACTO plus BEZLO also reduced CDI
8 recurrence rates, but the addition of ACTO did not
9 have an efficacy benefit over administration of
10 BEZLO alone.

11 As indicated before, in MODIFY I, ACTO alone
12 was discontinued at the interim analysis for both
13 efficacy and safety findings. Given the primary
14 efficacy findings, BEZLO was selected as the
15 product for licensure. From this point on, I will
16 present efficacy data related to BEZLO and placebo
17 only.

18 This graph presents cumulative rate of CDI
19 recurrence by weeks post-infusion. Gray line shows
20 the cumulative incidence of CDI recurrence in the
21 placebo arm, and the blue line shows the incidence
22 in the BEZLO arm.

1 As seen here, impact of BEZLO on reducing
2 CDI recurrence rate became apparent soon after
3 infusion. The difference between the recurrence
4 rates in placebo and BEZLO increased by week 4, and
5 remained consistent through week 12, resulting in
6 highly significant efficacy in reducing CDI
7 recurrence in the BEZLO group.

8 This is a forest plot where the differences
9 between CDI recurrence rates and BEZLO and placebo
10 recipients in the integrated dataset are shown for
11 the two stratification factors in the trials.

12 The horizontal lines show the 95 percent
13 confidence interval for the absolute difference in
14 recurrence rates, with the point estimate of the
15 difference as the diamond shape in the center of
16 the horizontal line. The vertical line intersects
17 zero on the X axis, indicating where the point
18 estimate would lie if there was not difference
19 between the CDI rates between BEZLO and placebo
20 arms.

21 The horizontal lines that fall to the left
22 of the vertical line demonstrate a difference

1 favoring BEZLO, meaning that the CDI rate is lower
2 in the BEZLO arm compared to placebo.

3 As data show, the differences in CDI
4 recurrence rates were in favor of BEZLO in all
5 strata. BEZLO arm had lower recurrence rate
6 compared to the placebo arm, irrespective of
7 hospitalization status and standard of care
8 antibiotics received. Reduction in CDI recurrence
9 rates in each stratum was consistent with the 10
10 percentage point absolute reduction seen in the
11 overall population.

12 In the fidaxomicin stratum, given the small
13 sample size, 95 percent confidence interval is wide
14 crossing over zero, but the point estimate
15 indicates a difference favoring BEZLO consistent
16 with other strata.

17 This graph shows CDI recurrence rates among
18 placebo recipients in the integrated MODIFY I plus
19 II dataset among the important subgroups at high
20 risk for CDI recurrence.

21 As gray bars indicate, CDI recurrence rates
22 were high in the high-risk groups, reaching 28

1 percent in immunocompromised patients, 31 percent
2 among those 65 years of age and older, 34 percent
3 among those infected with 027 strain, 41 percent
4 among those who had at least one previous CDI
5 episode over the past 6 months, and 42 percent
6 among those who had at least 2 episodes in the
7 past.

8 As presented in the blue bars, BEZLO
9 resulted in a substantial reduction in CDI
10 recurrence rates compared to placebo in all the
11 subgroups, including those risk groups with higher
12 recurrence rates.

13 The forest plot on this slide is another
14 demonstration of the data that I just presented.
15 It shows the differences in CDI recurrence rates
16 between BEZLO and placebo arms in the subgroups at
17 higher risk for a CDI recurrence. Seventy-six
18 percent of the patients had at least one risk
19 factor.

20 As seen here, in all the subgroups, efficacy
21 data favored BEZLO, meaning BEZLO resulted in a
22 robust reduction of CDI recurrence rate compared to

1 placebo. The difference in CDI recurrence rates
2 was at or above the 10 percentage point absolute
3 difference seen in the overall population.

4 In summary, each of the phase 3 trials
5 demonstrated that BEZLO is superior to placebo in
6 preventing CDI recurrence, and the treatment effect
7 is remarkably consistent between the trials. In
8 addition, BEZLO consistently reduces CDI recurrence
9 rates compared to placebo across important
10 subgroups at high risk for recurrence.

11 Now, I would like to revisit the endpoint
12 definitions and discuss additional analyses
13 conducted to assess the robustness of the primary
14 efficacy results.

15 In order to have CDI recurrence, a patient
16 must first achieve clinical cure of the baseline
17 episode. Rather than randomizing patients in the
18 study who had already achieved clinical cure of the
19 baseline CDI episode, we randomized and treated
20 patients during standard of care therapy of the
21 baseline episode.

22 This is because, for prevention of CDI

1 recurrence it was important for the monoclonal
2 antibody to be present before at-risk period for
3 recurrence begins, which is immediately after
4 standard of care therapy ends.

5 Due to this design feature, subjects who did
6 not achieve clinical cure, as defined in the
7 protocol, shown in black circle, could not be
8 counted as recurrence. This is approximately 20
9 percent of the population.

10 In the presence of standard of care
11 antibiotic, which is very effective in treatment
12 CDI, BEZLO was not expected to impact the clinical
13 cure rate, and indeed it did not as we'll see in a
14 moment.

15 Nevertheless, to assess the impact of the
16 post-randomization event of clinical cure on the
17 primary efficacy results, we conducted sensitivity
18 analyses. Global cure, as mentioned before, is the
19 secondary endpoint of the study, defined as
20 achieving clinical cure and having no subsequent
21 recurrences.

22 It is a supportive measure of the treatment

1 effect of BEZLO. It also supports the robustness
2 of the primary analysis because unlike the primary
3 analysis, which counts subjects who did not achieve
4 clinical cure as treatment successes, the global
5 cure analysis takes the opposite approach and
6 counts such subjects as treatment failures.

7 Before we look at the results of global
8 cure, we need to understand the results of clinical
9 cure, so let's look at the clinical cure data.

10 As seen here, efficacy of the standard of
11 care antibiotic was not impacted by administration
12 of BEZLO. Consistent with the idea that this
13 endpoint is not expected to be impacted by BEZLO,
14 in one trial, MODIFY I, the clinical cure rate was
15 slightly higher in placebo versus BEZLO arm,
16 whereas in the other, MODIFY II, the clinical cure
17 rate was higher in the BEZLO arm versus placebo.

18 The differences between the arms in each
19 trial were small, similar in magnitude, and
20 opposite direction. The differences were not
21 statistically significant or clinically meaningful.

22 In the integrated dataset, MODIFY I plus II,

1 the rates were nearly identical, 80 percent
2 clinical cure rates in the BEZLO and placebo arms.
3 In the presence of standard of care antibiotics for
4 CDI, BEZLO does not improve or diminish clinical
5 cure rates.

6 Here are the data for global cure. Analysis
7 of the integrated dataset was prespecified to
8 provide increased precision for estimating
9 treatment effect for this endpoint. However, this
10 endpoint is a composite endpoint, which includes
11 both clinical cure, which BEZLO has no effect on,
12 and CDI recurrence.

13 As mentioned before, patients without
14 clinical cure are considered a failure for global
15 cure, which makes this a less specific endpoint for
16 the intended indication, but allows us to assess
17 robustness of the primary endpoint.

18 BEZLO resulted in higher global cure rates
19 compared to placebo. The difference in global cure
20 rates favoring BEZLO reach statistical significance
21 in MODIFY II and the integrated dataset from both
22 trials.

1 CDI recurrence and global cure endpoints
2 have advantages and disadvantages in assessing
3 treatment effect on prevention of CDI recurrence.
4 CDI recurrence endpoint is a more appropriate
5 measure to assess efficacy of therapy that does not
6 treat the incident CDI, but only prevents CDI
7 recurrence, whereas global cure is a more
8 appropriate measure to assess efficacy of therapy
9 that does not only prevent CDI recurrence, but also
10 treats the incident CDI episode.

11 These two endpoints lie on the two extremes
12 of measuring treatment effect because CDI
13 recurrence counts patients who do not achieve
14 clinical cure as not having CDI recurrence, and
15 global cure counts such patients as having CDI
16 recurrence. The way clinical cure failures are
17 counted in either endpoint is not completely
18 representative of the true rate of CDI recurrence.

19 Since BEZLO dosing was not mandated to occur
20 at the point of clinical cure of the incident CDI
21 episode, both the CDI recurrence and global cure
22 endpoints are impacted by the definition of

1 clinical cure.

2 We have conducted sensitivity analyses to
3 explore the robustness of CDI recurrence endpoint.
4 Sensitivity analyses focused on the impact of
5 clinical cure or the impact of incomplete data on
6 CDI recurrence.

7 The first set includes assessment of CDI
8 recurrence in the subset of patients who achieved
9 clinical cure, an assessment of CDI recurrence in
10 the full analysis set using an expanded definition
11 of clinical cure.

12 We also assessed global cure using the
13 expanded clinical cure definition. In a moment, I
14 will present the sensitivity analyses conducted to
15 evaluate impact of incomplete data on primary
16 efficacy.

17 First, let's look at the results from the
18 CDI recurrence analysis in the subset of patients
19 who achieved clinical cure. Perhaps the most
20 natural endpoint, given the impact of clinical cure
21 on CDI recurrence, is to look at CDI recurrence in
22 the subset of patients who achieved clinical cure

1 rather than the full analysis set.

2 In other words, the denominator for this
3 assessment of recurrence is the subset of clinical
4 cure, not all subjects in the full analysis set.
5 This endpoint was a prespecified secondary analysis
6 in both trials. This analysis provides critical
7 supportive information in interpreting primary
8 efficacy.

9 The graph here shows that, among those who
10 achieved clinical cure, BEZLO significantly reduced
11 the proportion of subjects with CDI recurrence as
12 compared to placebo. The absolute differences
13 between treatment arms are consistent with the
14 primary analysis.

15 Recall the protocol definition of clinical
16 cure. Subjects had to receive 14 or fewer days of
17 standard of care therapy and have no diarrhea for
18 the 2 consecutive days immediately after completion
19 of standard of care therapy.

20 The reason for using this definition of
21 clinical cure was to standardize standard of care
22 duration and the follow-up period for recurrence

1 across patients. This definition resulted in a
2 larger than expected proportion of subjects failing
3 to achieve clinical cure. with The incidence of
4 clinical cure was approximately 80 percent in
5 MODIFY I plus II, versus approximately 90 percent
6 in the fidaxomicin phase 3 studies, which used
7 investigator assessment for clinical cure.

8 As a result, approximately 20 percent of
9 patients in the MODIFY program FAS population were
10 imputed as success for CDI recurrence and failure
11 for global cure. These were the 20 percent of
12 patients represented by the black circle in our
13 previously shown diagram.

14 It should be noted, however, that even
15 though 20 percent of subjects did not achieve
16 clinical cure by the protocol definition, the vast
17 majority of those patients did eventually achieve
18 clinical cure on study.

19 In fact, by expanding the clinical cure
20 definition, 95 percent of subjects achieved
21 clinical cure, and we were able to assess CDI
22 recurrence for all those patients. That is what

1 our second sensitivity analysis does.

2 This sensitivity analysis used an expanded
3 definition of clinical cure, in which patients with
4 no diarrhea on two consecutive days after
5 completion of any duration of standard of care
6 therapy were considered to have clinical cure.

7 This definition is more clinically relevant
8 for patients and prescribers, as it does not
9 exclude patients who receive standard of care for
10 longer durations or resolved diarrhea at a later
11 time point.

12 This sensitivity analysis with an expanded
13 definition of clinical cure minimizes the number of
14 patients for whom CDI recurrence is imputed as
15 success or failure and also uses all observed data
16 on the presence or absence of CDI recurrence in the
17 two trials.

18 This graph shows time to clinical cure using
19 the expanded definition. The blue line shows BEZLO
20 group and the dotted gray line shows placebo group
21 in MODIFY I. The majority of patients achieved
22 clinical cure by the third week after infusion,

1 which corresponds to the time frame in which their
2 standard of care therapy is ending, just a few days
3 beyond the window allowed by the protocol
4 definition of clinical cure.

5 As seen here, time to clinical cure rate is
6 nearly identical between BEZLO and placebo. There
7 are days when the proportion of patients achieving
8 clinical cure is slightly higher in the BEZLO
9 group, and other days when it is slightly higher in
10 the placebo group.

11 By week 3, proportion of patients who
12 achieved clinical cure exceeds 90 percent in both
13 treatment groups and reaches a plateau. This
14 allows nearly all patients to be assessed for CDI
15 recurrence for at least 9 weeks, which is ample
16 time for CDI recurrences to be observed.

17 As seen here, BEZLO does not impact a
18 patient's likelihood to achieve clinical cure or on
19 the timing to develop clinical cure. Data from
20 MODIFY II on this slide indicate that time to
21 clinical cure using the expanded definition is
22 nearly superimposable to what was seen in MODIFY I,

1 demonstrating that BEZLO does not impact clinical
2 cure.

3 Here, clinical cure rates using the original
4 definition and expanded definition by week
5 post-infusion are shown for MODIFY I and II. In
6 both trials, great majority of the patients
7 achieved clinical cure in both trials by week 3,
8 reaching 93 to 95 percent by week 6. Clinical cure
9 rates were similar in the treatment arms at various
10 time points.

11 We applied this expanded definition of
12 clinical cure to the assessment of primary
13 endpoint, CDI recurrence, in the full analysis set.
14 Despite an increase in CDI recurrence rates across
15 all subgroups, all groups, the absolute difference
16 between the treatment groups was maintained with
17 highly significant p-values.

18 On this slide, you see global cure rates
19 calculated using the expanded definition of
20 clinical cure. The proportion of patients
21 achieving global cure increased and a substantial
22 difference between the treatment groups is

1 observed. By week 3, at which time over 90 percent
2 of patients had achieved clinical cure, the
3 difference between treatment groups was highly
4 significant in both trials.

5 Using the more clinically meaningful
6 expanded definition of clinical cure, global cure
7 rates are not influenced by the small differences
8 seen in clinical cure rates as an artifact of the
9 strict definition of clinical cure used originally.

10 On this forest plot, you see for MODIFY I
11 and II separately a summary of the primary endpoint
12 and the sensitivity analyses conducted. In all
13 sensitivity analyses, BEZLO resulted in reduction
14 in CDI recurrence rates consistent with the overall
15 primary efficacy analyses, indicating robustness of
16 the primary endpoint.

17 The robustness of primary endpoint was also
18 assessed by evaluating the impact of incomplete
19 data on primary efficacy. Incomplete data included
20 patients who had incomplete follow-up or diarrhea
21 following clinical cure that was not tested for
22 toxigenic *C. difficile*.

1 As I previously showed, the majority, 85
2 percent of patients, completed the full 12-weeks
3 follow-up period. In fact, 92 percent of patients
4 had at least 4 weeks of follow up. Incomplete
5 follow-up was mainly due to deaths, withdrawal of
6 consent, or loss to follow-up.

7 Eighty-six percent of all of diarrhea
8 recurrences were tested for toxigenic *C. difficile*.
9 Of those not tested, the majority, 78 percent, had
10 only 1 or 2 days of diarrhea. We also assessed
11 patients who did not have CDI recurrence but
12 received a CDI active therapy during follow up.

13 In order to evaluate impact of incomplete
14 data, we prespecified an exploratory endpoint that
15 is diarrhea recurrence. In this endpoint, all
16 recurrences of diarrhea were included, irrespective
17 of whether the test for toxigenic *C. difficile* was
18 negative or not performed.

19 In addition to diarrhea recurrence endpoint,
20 three different sensitivity analyses were
21 conducted. And these patients with possible
22 incomplete data were imputed as failure for CDI

1 recurrence and were added to the primary endpoint
2 cases.

3 These analyses imputed the following
4 patients as having CDI recurrence; those who
5 discontinued from study, those who discontinued
6 from study and/or had diarrhea with no toxigenic *C.*
7 *difficile* test in the follow-up period, and those
8 who discontinued from study and/or had diarrhea
9 with no toxigenic *C. difficile* test and/or received
10 any dose of a potential CDI active therapy in the
11 follow-up period.

12 Here are the efficacy data for recurrence of
13 diarrhea irrespective of etiology. As expected,
14 the rates of diarrhea recurrence were higher than
15 the rates for CDI recurrence, but the treatment
16 differences observed for CDI recurrence in the
17 primary analyses are supported by these data.
18 BEZLO resulted in significantly lower diarrhea
19 recurrence rates compared to placebo.

20 Here are the results from the primary
21 efficacy endpoint and diarrhea recurrence
22 endpoints, shown on the forest plot. The

1 consistency of efficacy in diarrhea recurrence with
2 the primary endpoint demonstrates robustness of the
3 primary efficacy.

4 Now let's add the results from the
5 sensitivity analyses that evaluated impact of
6 incomplete data. Consistent with previous
7 findings, these analyses also indicate reduction in
8 CDI recurrence in favor of BEZLO.

9 In summary, multiple prespecified endpoints
10 and sensitivity analyses assessing impact of
11 clinical cure on CDI recurrence, and impact of
12 incomplete data consistently demonstrate robustness
13 of the primary endpoint of CDI recurrence and
14 efficacy of BEZLO in reducing CDI recurrence.

15 Similar to the data from individual trials,
16 the integrated dataset also demonstrate consistency
17 of efficacy findings from sensitivity analyses with
18 the primary efficacy results and indicate that the
19 primary efficacy of BEZLO is robust.

20 In conclusion, a single dose of
21 10-milligram-per-kilogram BEZLO is superior to
22 placebo in preventing CDI recurrence through

1 12-weeks follow-up period in patients receiving
2 standard of care antibiotics for CDI. Bezlotoxumab
3 reduced CDI recurrence rate by approximately 40
4 percent relative to placebo. And efficacy is
5 consistent across MODIFY I and MODIFY II.

6 Furthermore, across important
7 subpopulations, BEZLO consistently reduces CDI
8 recurrence rate compared to placebo.

9 Multiple prespecified and post hoc
10 sensitivity analyses consistently demonstrate that
11 assessment of the primary endpoint of CDI
12 recurrence and efficacy of BEZLO in reducing CDI
13 recurrence are robust. And finally, efficacy of
14 the standard of care antibiotic in achieving
15 clinical cure is not diminished by BEZLO.

16 Now I will hand it over to my colleague, Dr.
17 Yoshi Murata who will present the safety data.

18 Yoshi?

19 **Sponsor Presentation - Yoshi Murata**

20 DR. MURATA: Thank you, Dalya. I'm Yoshi
21 Murata, clinical director in infectious diseases at
22 Merck. I will now present the safety overview of

1 bezlotoxumab.

2 The safety assessments performed by the site
3 investigators during the MODIFY I and II trials are
4 shown on this slide. During the protocol-specified
5 monitoring period after the study drug infusion,
6 the following adverse events were recorded:
7 infusion specific adverse events reported on the
8 day or day after infusion; non-serious adverse
9 events reported during the first 4 weeks following
10 infusion; and serious adverse events and deaths
11 reported during the 12 weeks after infusion.

12 The safety monitoring also included
13 protocol-specified vital sign measurements,
14 electrocardiograms pre- and post-infusion, physical
15 examinations, and monitoring of clinical laboratory
16 parameters. Laboratory results determined by the
17 study investigator to be clinically relevant were
18 recorded as adverse events.

19 To assess the immunogenicity potential for
20 BEZLO, anti-drug antibody levels were measured at
21 baseline at prespecified time points during the
22 trial. The safety assessment data were then used

1 to characterize the safety profile of BEZLO.

2 In the next several slides, I will summarize
3 the results of the safety monitoring during the
4 MODIFY I and II trials.

5 The immunogenicity risk of BEZLO was
6 expected to be low because BEZLO is a fully human
7 monoclonal antibody. After administration of BEZLO
8 alone or in combination with ACTO, no anti-BEZLO
9 toxin of antibodies, either binding or
10 neutralizing, were detected in any of the 96
11 healthy subjects in phase 1 trials, including 29
12 subjects who received 2 doses given 3 months apart
13 or in subjects with Clostridium difficile infection
14 in phase 2 and phase 3 trials. The administration
15 of BEZLO is not associated with a generation of
16 binding or neutralizing anti-drug antibodies.

17 On this slide, a summary of the most common
18 infusion specific adverse events that were reported
19 on the day or day after infusion is shown. This
20 and other analyses to be shown in successive slides
21 was based on the all-patients-as-treated population
22 of the MODIFY I and II integrated dataset.

1 The safety profiles of subjects treated with
2 BEZLO are compared to those who received placebo.
3 As supporting safety data, the safety profile of
4 subjects treated with BEZLO with actoxumab are also
5 presented. It should be noted that subjects
6 enrolled in MODIFY I and II trials were treated
7 with standard of care antibiotics for their CDI at
8 time of enrollment and infusion of placebo, BEZLO,
9 or ACTO plus BEZLO.

10 The adverse events reported during the phase
11 3 trials are expected to include those commonly
12 seen in CDI subjects following treatment with
13 standard of care antibiotics.

14 Specific adverse events to be monitored
15 during and shortly after the study drug infusion
16 were prespecified in the MODIFY I and II protocols
17 to ascertain if hypersensitivity reactions may be
18 associated with such infusions.

19 As shown on this slide, the incidence of
20 infusion-specific adverse events was similar across
21 treatment groups. Also, there were no clinically
22 relevant trends in changes in ECG parameters of

1 vital signs between pre- to post-infusion
2 measurements. The majority of the infusion-
3 specific AEs were mild to moderate in intensity.
4 No anaphylactic, anaphylactoid, or hypersensitivity
5 reactions are observed.

6 The summary of adverse events during the
7 first 4 weeks following infusion is shown on this
8 slide. Approximately 60 percent of subjects
9 experienced 1 or more adverse events during the 3
10 treatment groups during the first 4 weeks following
11 infusion. Approximately 4 percent of subjects in
12 each treatment group died during the first 4 weeks
13 following infusion.

14 The proportion of subjects who experienced
15 drug-related adverse events and those with serious
16 drug-related adverse events were relatively low and
17 were comparable across treatment groups. There
18 were no association detected between BEZLO
19 administration and changes in clinical laboratory
20 parameters.

21 The most common adverse events reported
22 during the first 4 weeks following infusion are

1 shown on this slide. For this and other slides to
2 follow, the adverse events are listed by specific
3 incidence cutoff values, as shown on the bottom of
4 each slide and then shown in order of decreasing
5 incidence rate in the placebo group.

6 The most common adverse event was
7 Clostridium difficile infection, which was to be
8 reported as an adverse event only if it was
9 serious. CDI was noted in a higher proportion of
10 subjects in the placebo group than in the BEZLO or
11 ACTO plus BEZLO groups.

12 Given the previously discussed efficacy
13 results for BEZLO, to reduce the CDI recurrence
14 rates in the MODIFY I and II trials, this
15 observation is not unexpected. The incidence of
16 adverse events other than CDI was similar across
17 treatment groups during the first 4 weeks following
18 infusion.

19 I will now discuss the serious adverse
20 events, including deaths that were reported during
21 the 12 weeks following infusion, a summary of which
22 is shown on this slide. Across the three treatment

1 groups, approximately 30 percent of subjects
2 experienced serious adverse events. Approximately
3 7 to 8 percent of subjects across treatment groups
4 died during the 12 weeks.

5 There were 3 subjects who had drug-related
6 serious adverse events assessed by the investigator
7 to be related to study medication and who died
8 during the 12 weeks following infusion. Of these 3
9 subjects, 1 received BEZLO and experienced cerebral
10 hemorrhage with fatal outcome. The other 2
11 subjects received ACTO plus BEZLO and the adverse
12 events of fatal outcome were sepsis, hypoglycemia
13 and respiratory arrest for 1 subject, and small
14 bowel obstruction for the other subject. All 3
15 subjects had been hospitalized for serious medical
16 conditions at the time of diagnosis and study
17 entry.

18 The serious adverse events reported during
19 the 12 weeks following infusion are summarized on
20 this slide. The most common serious adverse event
21 was Clostridium difficile infection followed by
22 sepsis, both of which were noted in a higher

1 proportion of subjects in the placebo group than in
2 the BEZLO or ACTO plus BEZLO groups. The incidence
3 of other frequently reported serious adverse events
4 was generally similar across groups.

5 For additional analyses of the serious
6 adverse event profile of bezlotoxumab subjects
7 experiencing one or more of the following cardiac
8 failure adverse event terms, the preferred terms.
9 Cardiac failure, cardiac failure acute, cardiac
10 failure chronic, and cardiac failure congestive
11 were counted once and categorized as experiencing
12 cardiac failure.

13 A total of 41 subjects experienced a serious
14 adverse event of cardiac failure, of which 7 were
15 in the placebo group versus 17 in each of the
16 active treatment groups. To further characterize
17 this observed numerical imbalance of subjects
18 experiencing cardiac failure, a series of analyses
19 were performed.

20 The baseline characteristics of subjects who
21 experienced a serious adverse event of cardiac
22 failure are shown on this slide. As compared to

1 the overall all patients as treated population,
2 such subjects were older and almost all were
3 inpatients at the time of enrollment, with a higher
4 incidence of comorbid conditions and a higher rate
5 of severe CDI.

6 Across the treatment groups, nearly 90
7 percent had a medical history of any cardiac system
8 organ class condition, and approximately 70 percent
9 had a history of cardiac failure and/or
10 cardiomyopathy. Overall, this was an extremely ill
11 patient population with advanced age.

12 The safety profile of the 41 subjects with
13 cardiac failure was analyzed with respect to timing
14 to cardiac failure event. In the placebo group, 5
15 of 7 subjects experienced a cardiac failure event
16 before week 4, while in the BEZLO and ACTO plus
17 BEZLO groups the majority of such events occurred
18 after week 4. None of the cardiac failure events
19 was deemed drug related by the investigator.

20 A higher proportion of subjects in the
21 placebo group than in the BEZLO or ACTO plus BEZLO
22 group died before week 4. Their events were often

1 associated with concurrent conditions, such as
2 infection and a worsening CDI that are known to
3 exacerbate congestive heart failure, further
4 supporting the assessments that these events were
5 not drug related.

6 This slide places the cardiac safety data
7 shown on the previous two slides in the context of
8 available preclinical data for BEZLO. BEZLO
9 targets a non-endogenous bacterial toxin. BEZLO is
10 distinct from monoclonal antibodies with known
11 cardiac signal and which functionally interact with
12 endogenous target molecules.

13 There was no tissue cross-reactivity of
14 BEZLO in mouse and human tissues tested in vitro.
15 In repeat dose toxicity studies of BEZLO in mice,
16 there were no histological findings in cardiac
17 tissue or changes in hemodynamic parameters. Taken
18 together, there is no evidence of preclinical
19 cardiac safety findings with bezlotoxumab.

20 To further evaluate the cardiac safety
21 profile of bezlotoxumab, 325 subjects with
22 congestive heart failure at baseline as indicated

1 on the Charlson Comorbidity Index were identified.
2 This group of subjects will be called the CHF
3 subset, and a summary of the baseline factors is
4 shown on this slide.

5 The baseline factors are not entirely
6 balanced across treatment groups. More subjects in
7 the BEZLO group had higher Charlson Comorbidity
8 Index scores at or above 5 and were receiving
9 diuretic therapy. Not unexpectedly, the CHF subset
10 was an elderly population with a higher proportion
11 of inpatients and with more comorbid conditions
12 than the overall population.

13 The safety of the CHF subset to week 4 and
14 week 12 post-infusion is summarized on this slide.
15 At week 4, there were more adverse events observed
16 in the BEZLO group than in placebo or ACTO plus
17 BEZLO groups. However, the incidence of cardiac
18 adverse events was comparable with 10 to 11 percent
19 among the 3 groups. There were more deaths
20 observed in the BEZLO containing groups than in the
21 placebo group.

22 This imbalance correlates with a difference

1 in the numbers of deaths across the non-cardiac
2 categories, including neoplasm, renal and urinary
3 disorders, and respiratory disorders. There was no
4 appreciable difference in the number of cardiac
5 deaths across all treatment groups in the CHF
6 subset. At week 12, the overall trend of serious
7 adverse events and deaths seen across treatment
8 groups was similar to those at week 4 and with
9 increasing numbers. Again, most of the deaths were
10 due to non-cardiac causes and consistent with
11 pre-existing comorbidities.

12 In the CHF subset, all cardiac serious
13 adverse events through week 12 were reviewed and
14 deemed consistent with poor underlying cardiac
15 health, often with precipitating events such as
16 infection or anemia, leading to worsening cardiac
17 status. None of the cardiac serious adverse events
18 was drug related.

19 The conclusions from the safety analysis of
20 bezlotoxumab are as follows. A single infusion of
21 bezlotoxumab therapy in patients 18 years or older
22 and receiving antibiotic therapy for CDI is

1 generally well tolerated.

2 Bezlotoxumab has a safety profile that is
3 similar to that for placebo. The overall incidence
4 of adverse events in the bezlotoxumab treatment
5 group was comparable to the placebo group. In
6 summary, BEZLO has a favorable safety and
7 tolerability profile.

8 I will now invite Professor Mark Wilcox to
9 present the benefit-risk profile for bezlotoxumab.

10 Mark?

11 **Sponsor Presentation - Mark Wilcox**

12 DR. WILCOX: Hello. Good morning. Thank
13 you for the opportunity to speak today. I'm not
14 going to read through my roles that have been
15 already talked about and are up on the slide here.
16 But what I would like to emphasize is that I've
17 spent a considerable proportion, indeed the
18 majority of the last decade of my professional
19 career, dealing with C. difficile at a local,
20 regional, and national level, as those roles show
21 there.

22 I'm also involved internationally in C. diff

1 infection. I'm the only non-North American author
2 on the 2010 IDSA SHEA guidelines. And similarly,
3 I'm the only non-North American author on the
4 currently revised version of the same guidelines.

5 The reason I particularly wanted to be here
6 today is that I passionately believe that patients
7 should have better treatment options than are
8 currently available for CDI, and I'd like to
9 explain why I think that's the case. So I'm going
10 to talk about patient perspective, medical
11 perspective and societal perspectives in terms of
12 unmet needs, so I'm going to start, quite rightly,
13 with the patient perspective of unmet need.

14 So patients with CDI suffer from a
15 debilitating, life-changing, painful diarrhea that
16 can lead to other complications as well. And the
17 key point from a patient perspective is that there
18 are no optimal treatment options for recurrent CDI.
19 That's where the need is from a clinical
20 perspective.

21 Out of every 10 patients with CDI -- and
22 I've colored the patients here green and red

1 appropriately -- approximately 4 have an
2 unsatisfactory outcome. The minority of those 4 is
3 a failure to achieve a clinical cure.

4 The majority of those 4 with unsatisfactory
5 outcome is because of recurrent CDI. Even worse,
6 by day 30, between 1 in 6 and 1 in 16 patients are
7 dead after the diagnosis of CDI. Those data come
8 from large and indeed national datasets.

9 Despite this unacceptable situation from a
10 patient perspective, there are 2 plus 1, the plus 1
11 being metronidazole, which is not formally FDA
12 approved, therapeutic options for CDI, which is
13 unsatisfactory.

14 Indeed, as has already been pointed out,
15 there are no approved therapies for the prevention
16 of CDI recurrence. And ironically, antibiotic
17 treatment for CDI doesn't prevent recurrence, and
18 indeed it may exacerbate the risk because of the
19 damage to the gut microbiota.

20 Bezlotoxumab offers here something different
21 from a patient perspective, a novel approach not
22 based on antimicrobial therapy per se, to blocking

1 the untoward events following of toxin production.

2 From a medical perspective, CDI is clearly a
3 global health problem and indeed it's increasing in
4 incidence in the U.S., in Canada and in multiple
5 European countries, Spain, Germany, Eastern
6 European countries for example, CDI incidence
7 increasing. In the U.S., you've already seen some
8 of these data earlier, almost half a billion CDI
9 cases in 2011, nearly 30,000 associated deaths,
10 over 80,000 first recurrences, and over 50,000
11 follow-on additional recurrences. This is an
12 unacceptable medical burden of CDI.

13 If we now turn to the unmet medical needs in
14 respect of recurrent CDI, those episodes are
15 associated with a third increase in mortality, a
16 2 and a half fold increase in hospital readmission
17 rates, and a 4-fold increase in hospital
18 readmission days.

19 Together, that represents not only a very
20 significant medical patient burden, but a
21 significant cost burden. I haven't shown costs,
22 specific costs here. As you would expect, with a

1 condition like this, it's difficult to get an
2 accurate cost, but the range of costs associated
3 with CDI, indeed recurrent CDI, ranges from \$10,000
4 to tens of thousands of dollars per case.

5 What about the unmet societal need of CDI?
6 Well, not only the patient has to cope with the
7 illness, but the families have to cope with the
8 illness in terms of the debility, isolation and
9 loss.

10 What do I mean by debility? I'll give you
11 two prime examples. Patients with CDI are often
12 frightened to leave the house. That's because
13 they're frightened to be too far away from the
14 toilet. It's as basic as that. It's a very
15 unpleasant condition. They're worried about
16 recurrent symptoms.

17 It's known from work particularly carried
18 out by Kevin Garey's group in Houston, that anxiety
19 is a particularly prominent symptom, anxiety
20 because of the complications of CDI and anxiety
21 because of the current episode of CDI. This is a
22 debilitating condition. And indeed, few infectious

1 diseases arouse quite as much concern, and that
2 reflects, in my opinion, the protracted nature of
3 recurrent CDI. That's where the prime unmet need
4 is.

5 I'm going to show evidence to support the
6 next bullet points that families and patients often
7 use words like battle and war. Yes, they're
8 emotive terms, but they're emotive for good reason.
9 And indeed, it's notable the number of different
10 patient support groups that exist. I've only
11 listed some, not all, only some of the U.S.-based
12 patient support groups. And if we just ask
13 ourselves the simple question, why are there so
14 many patient support groups? There are many in
15 Europe, in the U.K. as well. I'll come back to
16 that point.

17 Here's an example of probably the most
18 well-known patient support group, U.S. support
19 group, namely the C Diff Foundation. This is their
20 home page detailing information about Twitter
21 activity. You can see that in the middle of the
22 slide. Also you note from this slide that the

1 C Diff Foundation is extremely active. It
2 organizes an annual meeting, which is well
3 attended.

4 I spoke at the last meeting in Boston. I'm
5 due to speak in the meeting advertised here in
6 Atlanta in the fall of 2016. An extremely
7 passionate group of individuals, why do they exist?
8 Because of the unmet needs relating to CDI. And I
9 put it to you that that's mainly because of
10 recurrent CDI, which blights people's lives.

11 The second example from those 3 support
12 groups that I listed two slides ago is this one, to
13 prove that the words battle and war are real words
14 used by real patients. The names of the patients
15 have been obscured, as I'm sure you realize why, on
16 this slide.

17 This is a screenshot of this case history
18 page from this support group taken last week. So
19 you can see the words on the right-hand side,
20 battle with the beast, where am I with this battle.
21 These are, again I put it to you, extremely emotive
22 terms, and I feel passionately for these patients

1 who have to put up with this disease.

2 Lastly on this slide, if you look at the far
3 right-hand side, look at the numbers of hits that
4 these sites and these case histories are
5 generating. Why? Because of the unmet need.

6 So I'd like to talk about the benefit-risk
7 assessment. We've heard that this is a single IV
8 dose of bezlotoxumab 10 milligrams per kilogram
9 given to patients aged at least 18 years of age,
10 whilst, at any point, which I think is a clinically
11 useful attribute, at any point during the standard
12 of care therapy for CDI.

13 On the right-hand side, I believe that the
14 data supports the fact that bezlotoxumab is
15 generally well tolerated with a similar profile to
16 that of placebo. On the left-hand side, from a
17 clinical perspective, the efficacy provided by
18 bezlotoxumab is the prevention of CDI recurrence
19 throughout the 3-month, 12-week at-risk period.
20 And I think you've been shown, I believe you've
21 been shown, clinically meaningful sensitivity
22 analyses that back up and confirm the consistency

1 of that reduction in CDI recurrence risk.

2 I think also importantly, the efficacy has
3 been demonstrated across predefined, multiple,
4 clinically relevant, clinically important subgroups
5 at high risk for recurrence. And on that last
6 point, that links to my first point on this slide.

7 You see the number needed to treat in those
8 at risk patients is 6. It's a very low NNT. But
9 contrast that with the NNT for the overall study
10 population of 1 in 10, which I still think,
11 believe, is a low NNT for the entire population
12 comprising those predefined as being at risk, but
13 also those not predefined as being at increased
14 risk.

15 We've heard that bezlotoxumab reduces CDI
16 recurrence by approximately 40 percent. If you
17 translate that into real-life potential, then the
18 number of potentially prevented CDI episodes,
19 recurrences, is 50,000 in the U.S., per annum,
20 recurrent.

21 Add to that the reduced CDI-related
22 readmissions and all-cause cumulative hospital

1 days, these data have been obtained by a post hoc
2 analysis of the phase 3 database that's being
3 talked about today. They're important clearly from
4 a medical perspective.

5 Add to that the fewer CDI cases that are
6 preventing recurrence that would therefore need
7 antibiotic treatment. And that then potentially
8 reduces the chance of antibiotic resistance, not
9 particularly in *C. diff*, but actually in other
10 organisms in the gut that are exposed to these
11 antibiotics. And we know that CDI treatments,
12 vancomycin and metronidazole for example, are both
13 associated with increased risk of VRE, last but not
14 least the potential benefits to other patients by
15 preventing recurrences and therefore the spread of
16 strains that can be harmful and indeed that
17 includes epidemic strains as well.

18 This is a reasonably busy slide on purpose.
19 It can get a lot worse than this, but I'm not going
20 to -- this is the simplified version, you'll be
21 relieved to know. On the left-hand side, you'll
22 see the complication of surgical aspects, and that

1 hasn't been talked about today. It's not really
2 relevant today to talk about that.

3 What I wanted to summarize briefly are the
4 other 3 major categories of outcomes shown on this
5 slide due to CDI. Recurrent CDI has rightly been
6 the theme of today's presentation and my
7 risk/benefit analysis.

8 I point out that between half and
9 three-quarters of first recurrences lead to new
10 readmissions, enormous patient, medical and
11 societal impact. The length of hospital stay data
12 is shown on the right-hand side of the slide, with
13 between 5 and 15 days increased length of stay due
14 to CDI. The mortality is shown at the bottom of
15 the slide. I'm not going to repeat that there.

16 But the common theme between the top, the
17 right-hand side, and the bottom of this slide is
18 recurrence. That drives to a greater or lesser
19 extent elements of each of those three major
20 outcome categories.

21 I'd like to summarize -- this is my final
22 slide -- by congratulating the CDC. I couldn't put

1 it better myself. I don't think anybody could.
2 This is the 2013 CDC document that has rightly
3 received so much airtime.

4 The quote from CDC is that, "C. diff is an
5 immediate public health threat that requires urgent
6 and aggressive action." I point out that this
7 document was published in 2013. Since it was
8 published, zero additional treatment options for
9 CDI have become available, approved options.

10 I'd like to summarize by saying that I
11 believe that bezlotoxumab helps to address unmet
12 patients' medical and societal needs due to CDI,
13 all three of which are clearly important and,
14 lastly, that bezlotoxumab has a positive benefit-
15 risk profile for the prevention of CDI recurrence.
16 That concludes this presentation. Thank you for
17 listening.

18 DR. KARTSONIS: Good morning. My name is
19 Nick Kartsonis. I am an infectious disease
20 clinician, and I serve as the section head for
21 antibiotics and CMV at Merck. And I'm going to
22 help with the redirection and the answering of the

1 questions during the clarification section. So we
2 turn it back to the committee.

3 **Clarifying Questions to the Presenters**

4 DR. BADEN: Thank you all for a wonderful
5 set of presentations covering a lot of data
6 encompassed by those studies.

7 At this time, I'll open the floor to the
8 members of the committee for clarifying questions
9 for the sponsor. Remember to state your name for
10 the record before you speak and, if possible,
11 direct to a presenter. Dr. Kartsonis will
12 facilitate the answering of questions. To members
13 of the committee, please look to Lauren to make
14 sure we acknowledge you and then can sequence the
15 questions properly. So Dr. Corbett?

16 DR. CORBETT: Thank you. This is just a
17 clarification on the efficacy discussion with Dr.
18 Guris, I believe it was, her slide 47 perhaps. I
19 just want to kind of hear again the discussion
20 about -- I wrote down 95 percent achieved clinical
21 cure during the study period and I want to make
22 sure that was what I heard.

1 DR. KARTSONIS: In the expanded clinical
2 cure definition, when we look at it, we do indeed
3 see an increase in the number of patients who
4 achieved clinical cure. In fact, if we can go to
5 the time of clinical cure slide, there you go,
6 slide 49, if you could, put the slide up for me,
7 please.

8 As you can see on this slide, which is from
9 the presentation, slide 49, indeed, by
10 approximately day 21, we are approaching 90, 95
11 percent of the patients. If you could look at the
12 numbers down below, 94 percent of the patients in
13 the 2 groups have achieved clinical cure with this
14 expanded definition.

15 DR. CORBETT: Thank you.

16 DR. BADEN: Building on that clarifying
17 question at this point, the basis for the initial
18 definition of clinical cure being 14 days, what was
19 the basis for that definition, and what is the
20 basis for this revised definition?

21 DR. KARTSONIS: Thank you for that question.
22 The original definition, as we noted, was based on

1 the receipt of -- and you can put the slide up.
2 Slide 47, we mentioned this.

3 The receipt of less than 14 days of standard
4 of care regimen, as well as no diarrhea for the
5 immediate 2 days following the completion of
6 standard of care therapy, that definition was
7 defined with an effort to standardize the amount of
8 follow-up period that the patients had actually
9 received.

10 As you can see there in the original study,
11 by doing that we indeed ensured that we would have
12 approximately 10 weeks of follow-up period for all
13 the patients in the study.

14 But clearly, what we found when we looked at
15 the data as to why patients had failed from the
16 clinical cure standpoint, there were really 2 main
17 reasons. One was that patients had received more
18 than 14 days of the regimen -- and I'll get back to
19 that in just a second -- and secondly was that the
20 patients had persistent diarrhea in the 2-day
21 period following the completion of that regimen.

22 What's interesting is that when you look at

1 the patients who got more than 14 days, there was a
2 common theme. In fact, we looked at all of those
3 patients who had more than 14 days of therapy, and
4 it turned out that, in 90 percent of them, you
5 could explain it based on four reasons.

6 The patients were either immunocompromised.
7 They were patients who had had prior episodes of
8 CDI. They were patients who were receiving a
9 concomitant antibiotic for another condition, or
10 they had an initial non-response to their regimen
11 very early in the first 3 days and required a
12 change in their regimen, which was allowed in the
13 study. We did allow for switches. It was not
14 common. It was only seen in about 6 percent.

15 So 90 percent of the patients in all the
16 treatment groups were for those particular reasons.

17 It wasn't because the patients had still
18 diarrhea. In fact, in 80 percent of those patients
19 who had received more than 14 days, they had
20 already resolved their diarrhea by the time they
21 had completed the standard of care regimen.

22 Furthermore, most of them had resolved it by

1 day 10 of the study. So the important point is
2 that the physicians felt it was important for them
3 to continue the regimen because they had other
4 factors that were driving the underlying condition.

5 The second reason that people failed was
6 because of the fact that they had persistent
7 diarrhea for the first two days following the
8 completion of standard of care. Well, it's not
9 uncommon in C. diff for patients to have trickling
10 of diarrhea for the first few days following the
11 completion of standard of care.

12 It's interesting that when we actually
13 looked at the data for those people, most of them
14 subsequently resolved their diarrhea by day 3, day
15 4, and in fact 75 percent of those people who still
16 had diarrhea in those first 2 days had resolved it
17 by 7 days following the completion of standard of
18 care.

19 So when you go back to that expanded
20 clinical cure definition, you really are
21 encompassing how, in our opinion, the patient is
22 feeling. And we think it's more clinically

1 relevant because it's taking into consideration the
2 fact that the investigator felt that the patient
3 needed that therapy, and they continued the
4 patients accordingly. And so that's why we've
5 presented that data today.

6 Again, as Dr. Guris nicely mentioned in her
7 presentation, this is based on all observed data.
8 Clinical cure was never evaluated by the
9 investigator. It was all programmatically assessed
10 by the company.

11 Since we have all the data, all the loose
12 stool data for 85 days of therapy, we can look at
13 the observed data as opposed to imputing patients
14 as potential failures for a CDI recurrence
15 definition or for the global cure definition. This
16 is, in our opinion, the purest way to look at
17 clinical cure, and in fact the best way to look at
18 the endpoints of both recurrence as well as local
19 cure.

20 DR. BADEN: Thank you. Dr. Daskalakis?

21 DR. DASKALAKIS: Demetre Daskalakis from New
22 York Department of Health, New York City Department

1 of Health. Just a question. The idea of
2 readmissions was mentioned. Have you looked at
3 readmissions among your hospitalized patients?

4 DR. KARTSONIS: Yes, we did. We actually
5 have a post hoc analysis that did that. I can
6 actually call Dr. Guris to the stand to present
7 that data. We did collect it systematically in our
8 studies. It wasn't a primary or secondary endpoint
9 of the study, but we did systematically collect it
10 and we can look at that data.

11 DR. GURIS: Slide up, please. So in this
12 analysis, we looked at patients who were inpatients
13 coming into the study. They were discharged from
14 hospital and then they were readmitted. And you
15 see overall the reduction, approximately 60 percent
16 between bezlotoxumab and placebo, 9.6 percent of
17 the placebo patients were actually readmitted for
18 CDI-associated reasons within the 30 days.

19 In BEZLO, it was 4 percent. We see 60
20 percent reduction, relative reduction in BEZLO
21 group compared to placebo. And we see consistent
22 results across different groups, including elderly,

1 those with one or more previous CDI episodes, and
2 severe CDI.

3 DR. BADEN: Dr. Goetz?

4 DR. GOETZ: I have a couple. This is
5 Matthew Goetz, VA and David Geffen School of
6 Medicine. I have two questions here. I'd like to
7 turn to -- let me get to my note here -- I guess
8 it's the impact of BEZLO on high-risk versus low-
9 risk populations, which was discussed, I think, in
10 slides 39 and 87.

11 What I'm interested in is sort of the
12 converse, the benefit of BEZLO in low-risk
13 populations rather than high-risk populations. So
14 I don't know if you -- one way of looking at that
15 would be populations that have had zero prior
16 episodes as were the benefit is there.

17 Then you have a series of -- you have a
18 slide that shows a series of parameters that define
19 high-risk populations and I'm interested in looking
20 at the inverse of that.

21 DR. KARTSONIS: Thank you. And here's just
22 a reminder to the committee of the high-risk

1 groups. As you can see, BEZLO did reduce it across
2 all of the high-risk groups. We did also look at
3 the converse and we have that data as well from the
4 groups.

5 Why don't we show that, please? Yes. Slide
6 up please.

7 Here's the full set of data for each of the
8 risk factors. You see both the high-risk and the
9 low-risk groups all shown on the same slide. And
10 indeed you can see in this forest plot, again just
11 to remind you how the forest plot's laid out, if
12 it's favoring bezlotoxumab it's on the left-hand
13 side for recurrence with the actual point estimate
14 shown as the diamond, and the 95 percent confidence
15 interval shown as the lines around that.

16 As you can see, in both high-risk as well as
17 in low-risk patients, we do see a consistent
18 effect. And in fact, in many of these, as you can
19 see, it excludes zero and it still remains
20 significant in both high risk and low risk. So we
21 actually think it's appropriate that bezlotoxumab
22 is made available to all patients, including low

1 risk as well as high risk. And in fact, as Dr.
2 Wilcox mentioned, a number needed to treat to
3 prevent one recurrence amongst all the patients was
4 as low as 10.

5 DR. GOETZ: To follow up on that a little
6 bit.

7 DR. KARTSONIS: Sure.

8 DR. GOETZ: If you look at people who have
9 none of the high-risk factors, you've looked at
10 each of the individual high-risk factors, but
11 still, people could have had one factor and not the
12 other. I don't know whether you looked at the data
13 in that fashion.

14 DR. KARTSONIS: Sure. Dr. Guris had
15 mentioned in her presentation that 74 percent of
16 the patients had one of the risk factors. And in
17 fact, if we look at the patients who had one or
18 more of the risk factors, there is a significant
19 reduction in the patients. In fact, it's a
20 difference between 30 percent having a high factor
21 of recurrence versus 17 percent. So the difference
22 is 13 percent absolute difference.

1 In the low-risk group, as you might expect,
2 the differences are smaller. It's about 3 percent.
3 And the confidence intervals do not exclude zero.
4 So we do see still an effect, but it's not as
5 pronounced as it is. The recurrence rates in the
6 BEZLO group in that situation are low, but it's
7 generally the same.

8 DR. GOETZ: Then I had one other question
9 about -- you've touched on it obliquely, but the
10 exposure of patient populations to antibiotics not
11 active against C. diff, as to whether that had any
12 impact on the efficacy of BEZLO.

13 DR. KARTSONIS: If I could ask a clarifying
14 question, do you mean sort of concomitant
15 antibiotic use?

16 DR. GOETZ: Concomitant antibiotic.

17 DR. KARTSONIS: Are you interested in the
18 data in recurrence or are you interested in
19 clinical cure, just curious there?

20 DR. GOETZ: Obviously globally, I'm
21 interested in both.

22 DR. KARTSONIS: Okay. So can we start with

1 the clinical cure data first and then we'll move
2 into the recurrence data, if that's okay. So,
3 indeed, if you could, put the slide up, please.

4 Approximately 40 percent -- this is actually
5 a high number -- 40 percent of the patients were
6 receiving concomitant antibiotics for another
7 bacterial condition while they had their C. diff
8 episode. As you can see, about 41 percent on
9 placebo, 37 percent, as you might expect, patients
10 who were receiving concomitant antibiotics did
11 worse from a clinical cure standpoint.

12 Now again, as I mentioned earlier, a lot of
13 these patients were patients who required more than
14 14 days of additional therapy and were thus being
15 counted, per the per protocol clinical cure
16 definition, as a failure. However, as you can see,
17 there's really no differences between the two
18 treatment groups, BEZLO versus placebo. And as
19 expected, the patients who weren't receiving
20 concomitant antibiotics had a higher response rate
21 as opposed to those who did receive concomitant
22 antibiotics.

1 We also do have the recurrence data. So
2 now, when we did this analysis, we actually looked
3 at concomitant antibiotics use after the patient
4 got clinical cure and during the follow-up period,
5 because that's the best way to then look to see if
6 the patients had that influence on their ability to
7 develop recurrence.

8 If we could put the slide up, please, you
9 can see there's about a third of the patients who
10 had concomitant antibiotic use after SoC. And in
11 that particular setting, you see that, irrespective
12 of whether or not they received concomitant
13 antibiotics or not, we still see a notable effect
14 for bezlotoxumab in both settings.

15 Let me orient you to the slide a second.
16 The concomitant antibiotic use is shown on the
17 left-hand side, about 35 or 36 percent. The people
18 who were receiving antibiotics following standard
19 of care, the placebo was 26 percent versus 16
20 percent on BEZLO, or 17 percent on BEZLO, and those
21 without was 27 versus 17 percent, so consistent
22 effects for bezlotoxumab both whether or not

1 patients had to go on and receive concomitant
2 antibiotic therapy or did not.

3 DR. BADEN: Building on that slide, the
4 antibiotics were anti-anaerobic all in the
5 assessment of the qualitative impact of the choice
6 of antibiotic?

7 DR. KARTSONIS: Sure. We haven't gone down
8 to the level of looking at the specific
9 antibiotics. We've really focused mainly on all
10 antibiotic therapy. This would be all concomitant
11 antibiotic use, but we didn't break it down if it
12 was for Gram-positives versus Gram-negatives versus
13 anaerobic.

14 But I can tell you from reviewing the data
15 and our team reviewing it, people received these
16 antibiotics for a lot of different conditions,
17 including both Gram-positive, Gram-negative, and
18 anaerobic conditions, and that's an important thing
19 to keep in mind because a lot of these people had
20 to then be re-exposed to metronidazole in the
21 follow-up period.

22 DR. BADEN: Dr. Moore?

1 DR. MOORE: Hi. So it wasn't specifically
2 stated, but I assume it was -- it seemed to be
3 implied. None of these patients received fecal
4 transplants during or after the study period?

5 DR. KARTSONIS: Sure. We did allow -- if
6 patients had had a prior episode and had received a
7 fecal transplant, they were still potentially
8 eligible if they now came in with another CDI
9 episode to receive bezlotoxumab and be enrolled in
10 the study. That happened in only one case.

11 But we did allow, once a patient had
12 developed recurrence, that in that setting they
13 could then go on and receive an FMT. FMT was not
14 allowed while the efficacy was under evaluation,
15 but if the physician determined that the patient
16 developed CDI recurrent and wanted to then allow
17 that in the follow-up period, they could indeed do
18 so.

19 We examined that data. It's actually very
20 fascinating data. What we found was that the use
21 of FMT in the follow-up period was significantly
22 higher in the people receiving placebo as opposed

1 to the people receiving either BEZLO or ACTO plus
2 BEZLO.

3 In fact, there were 23 patients in the
4 placebo group who went on to get FMT because of
5 their recurrence as opposed to only 4 in both of
6 the BEZLO as well as the ACTO plus BEZLO group.

7 Let me put that in a different way, that if
8 you compare it relative to all of the recurrences
9 that occurred in each of the groups, that would
10 have been 11 percent of the patients in the placebo
11 group who recurred went on to get FMT as opposed to
12 3 percent of the patients in the active groups.
13 That's an 80 percent reduction in the use of FMT by
14 giving bezlotoxumab.

15 DR. MOORE: Okay, that's a real
16 game-changer, and I think that has significant
17 implications. Do you have those data available for
18 evaluation?

19 DR. KARTSONIS: We actually recently did
20 these analyses. I don't have it available as a
21 slide for you, but we could prepare one for you and
22 share it after the lunch time meeting if you'd

1 prefer.

2 DR. MOORE: Thank you very much.

3 DR. KARTSONIS: You bet.

4 DR. MOORE: That would be great.

5 DR. BADEN: Dr. Weina?

6 DR. WEINA: Pete Weina from Walter Reed. I
7 noticed that the proposed dosing is for 60 minutes.
8 Was that chosen because it's longer than 30 and
9 less than 90? Or was there a specific reason and
10 if there was an evaluation as to any kind of
11 adverse events associated with less-than-60-minute
12 infusion rates?

13 DR. KARTSONIS: Sure. Thank you for that.
14 We've actually evaluated -- bezlotoxumab has only
15 been administered to patients in a range between 60
16 minutes and 120 minutes, so we don't have any data
17 with regard to its use over 30 minutes. Now, keep
18 in mind it is a large dose. It's given in a 200-mL
19 infusion. It does take some time to actually
20 deliver the drug. So we recommend and would be
21 recommending that we give it as we studied it,
22 which was over a 60-minute period.

1 I can tell you, when you compare 120 versus
2 60, there's no difference. We've looked at that in
3 a specific phase 1 study and didn't see any impact
4 with regard to either pharmacokinetics or even the
5 safety, but I don't have any data to provide you
6 with regard to less than 60 minute infusion.

7 DR. BADEN: Comments to the committee. If
8 any of you have a question that immediately builds
9 on the prior question, please raise your hand so
10 that we can follow any line of thinking before we
11 move on to multiple additional topics. Dr. Hilton?

12 DR. HILTON: I'm building on an earlier
13 question about the enhanced definition. And I
14 wonder if at baseline you know the history of
15 standard of care use in the previous two weeks, for
16 example.

17 DR. KARTSONIS: In terms of the actual way
18 the study was administered, we allowed for the
19 monoclonal therapy to be given at any time while
20 the patients were on standard of care, standard of
21 care therapy. I can tell you that the mean day of
22 administration of the study infusion and the median

1 day was day 3. So patients had already been on
2 standard of care on average about 72 hours prior to
3 receiving the standard infusion.

4 It did range over the course of the entire
5 period. In fact, 70 percent of the patients
6 received the standard of care within the first 4
7 days of the study. We did allow for it to be at
8 any time, but I think that also speaks to how
9 people want to use these agents.

10 Keep in mind a lot of these patients are in
11 the hospital setting and, while a patient is
12 getting better and as they're responding, they're
13 probably considering the patient to be discharged
14 home. It's an option for the patients to then get
15 their bezlotoxumab to be given as an administration
16 of therapy and then they can go home and administer
17 it accordingly.

18 We did not see any differences in terms of
19 clinical cure or recurrence based on the timing of
20 the study infusion relative to when the standard of
21 care antibiotic was administered.

22 DR. HILTON: I have a couple of other

1 questions.

2 DR. KARTSONIS: Sure.

3 DR. HILTON: In MODIFY I the global cure
4 rate difference was 5 percent, and in MODIFY II
5 it's 15 percent. And I'm trying to understand why
6 the difference was so much larger in MODIFY II.

7 Looking at the baseline characteristics, one
8 thing that comes to mind is region, country. And I
9 wonder if you have a forest plot to show us
10 differences in results of the two trials by region
11 of the world.

12 DR. KARTSONIS: Okay. Let me just take a
13 moment and talk about the global cure as we're
14 pulling up the data with regard to the data by
15 region. So it is true that, in MODIFY I, the
16 global cure difference was 5 percentage point and
17 in MODIFY II it was 15 percentage point. And a lot
18 of that, again, relates back to what the
19 differences were in clinical cure.

20 If you recall, there was a 4 to 5
21 percentage-point difference in MODIFY I in favor of
22 placebo, which then brings down the global cure

1 rate difference in MODIFY I. And then in MODIFY
2 II, there was a 5 percentage point advantage for
3 bezlotoxumab versus placebo. So if you add that to
4 the then 10 percentage-point difference for
5 recurrence, you get the 15 percentage-point benefit
6 that you're seeing in global cure.

7 Now again, when you look at the integrated
8 data, the differences in terms of clinical cure
9 were the same. And not surprisingly, the global
10 cure results when you look at the integrated data
11 are essentially the difference in recurrence, which
12 we feel also speaks to the value of -- that the
13 effect of bezlotoxumab is really on preventing
14 recurrence, not necessarily on impacting on their
15 initial episode.

16 But going on to your question, if you could
17 put the slide up, please, we did look at the global
18 cure by different regions, including the U.S.
19 versus ex-US. And you can see, there is an
20 advantage whether it's in the U.S. or ex-U.S., so
21 the difference isn't region. You can see the
22 difference was over 8.5 percentage points in the

1 U.S. and in the ex-U.S. was about 10 percentage
2 points.

3 So region didn't make a difference. And
4 this is again because there really was no
5 difference in terms of clinical cure when you look
6 at the totality of the data across the two studies,
7 which speaks to the fact that there were recurrence
8 differences if you look at a regional level of U.S.
9 versus ex-U.S.

10 DR. HILTON: My last question, thank you.
11 Just thinking in terms of -- we talk about
12 precision medicine nowadays and who should get a
13 specific treatment. And you talked about toxin
14 type A and B and that one of the treatments you
15 studied is targeted to A and the other is targeted
16 to B. Is there an assay for toxin type, and do you
17 know toxin types of the patients who were in the
18 studies?

19 DR. KARTSONIS: Sure. So there is -- I
20 mean, there are commercial assays that look at
21 toxin types, but it's not a readily-assessed test
22 in the clinical setting, and I turn to the

1 clinicians in the room to also speak to this issue.

2 People are not necessarily looking at their
3 C. diff at the level of is it producing toxin A
4 versus toxin B and how much of it is it producing?
5 And similarly they're not necessarily having
6 ribotype data that might be indicative of how much
7 toxin A or B that they have. So for example, if
8 they had 027 they might have potentially higher
9 levels of toxin A or toxin B.

10 So to answer your question, there really
11 isn't a tool that you can use from a toxin test
12 standpoint to look at this issue.

13 DR. BADEN: Dr. Follmann, you had a
14 follow-up question?

15 DR. FOLLMANN: I had a question that sort of
16 relates to what was talked about earlier at the
17 very start.

18 DR. BADEN: Did you have a follow-up
19 question, Dr. Moore, for this topic?

20 DR. MOORE: I do. Just a follow-up question
21 to Dr. Hilton's enquiry about toxin testing. Would
22 you be able to -- sorry. It's been recently

1 established that use of PCR for diagnosing patients
2 who have C. diff is a bit too sensitive and there's
3 discussion about scaling that back. In the U.K.
4 they're doing toxin testing, going back to the
5 toxin screening, sorry, the ELISA. Do you have any
6 data with regard to enrolling your patients as to
7 who was diagnosed by PCR?

8 DR. KARTSONIS: Let me explain to what we
9 allowed from a diagnostic standpoint so folks can
10 understand it. We allowed a number of different
11 tests that patients could be diagnosed based on C.
12 diff. I mean, we allowed -- obviously someone if
13 they had C. diff culture that was also in the
14 setting of toxin growth following the culture, we
15 allowed cell cytotoxicity assays. As you know,
16 both of these are sort of the gold standard, but
17 are very laborious to do.

18 So it's not surprising that the vast
19 majority of the patients in the study who got
20 enrolled actually got enrolled either to measure
21 toxin directly via an EIA test or to measure the
22 presence of the toxin gene with regard to PCR. In

1 fact, it was about 48 percent EIA, 48 percent PCR,
2 and the remainder were cell cytotoxicity assay- and
3 culture-based regimens.

4 We did look at the efficacy of bezlotoxumab
5 relative to what their entry criteria, and we still
6 see efficacy. We see efficacy I should say with
7 regard to bezlotoxumab, irrespective of whether or
8 not the test that they got enrolled on was an EIA,
9 which is probably a little bit more toxin specific,
10 as opposed to PCR, which as you mentioned has been
11 more called into question because you're
12 necessarily picking up -- you're only measuring the
13 potential of the presence of the toxin gene. That
14 said, the differences were significant irrespective
15 of whether or not it was EIA versus PCR.

16 DR. MOORE: Do you have data to show that?

17 DR. KARTSONIS: Sure, absolutely, if you
18 wouldn't mind putting the slide up for me, please.
19 This is the data with regard to EIA versus PCR.
20 Slide up, please. Thank you very much. You can
21 see there that we saw a greater effect with EIA
22 versus PCR. The difference, as you can see, was on

1 the order of about 45 percent relative risk
2 reduction with EIA versus about 28 percent if you
3 looked at PCR.

4 However, if you do a statistical test around
5 this, they're both significant and the confidence
6 intervals exclude zero. So it didn't matter
7 necessarily with regard to EIA versus PCR. We did
8 see efficacy in both of them.

9 DR. BADEN: Dr. Andrews?

10 DR. ANDREWS: I can see why -- I'm not a
11 clinician, totally not a clinician -- you're
12 spending a lot of time talking on the recurrence,
13 and did it recur, and whether the infection came
14 back, and it looks like it depends on how you look.
15 But for patients, they're very concerned about
16 symptoms, so I appreciate your description of how
17 many times are you having diarrhea. That's a
18 really important improvement in somebody's life.

19 A really bad outcome in somebody's life is a
20 death. And I know this was in the safety data, but
21 it occurred to me that you spend a lot of time
22 saying -- I don't see anything that just talks

1 about deaths. I see deaths among people with
2 adverse events or with heart failure, but I didn't
3 see any data, and maybe you have that, but these
4 are people with a lot of problems, so I get that.
5 But shouldn't there be a difference? Shouldn't you
6 see a lower number?

7 DR. KARTSONIS: We'd love all our therapies
8 obviously to not only have a clinical benefit but
9 also to produce a mortality benefit in our setting,
10 and, actually, if I could have slide 655, please.
11 This is the time to death, so you can see over the
12 course of the study the differences. If you could
13 put the slide up, please.

14 We did look at the time to death in the
15 study. And as you can see, about half the deaths
16 occur within the first 4 weeks. And about the
17 other half deaths occur between weeks 4 and weeks
18 12. There is no difference between the treatment
19 groups with regard to overall death. But I think
20 it's important to keep in mind the patient
21 population that we're treating here. We're
22 treating very sick elderly patients where their

1 mean age is over the age of 65.

2 We're following them for a
3 relatively -- which for some of these patients who
4 are 80 years plus, 3 months is a notable amount of
5 time of follow-up, and we did not see a difference
6 with regard to overall mortality. But you can see
7 here that there was no negative effect of giving
8 bezlotoxumab based on mortality.

9 DR. BADEN: C. diff-associated death,
10 C. diff-associated colectomy, any differences?

11 DR. KARTSONIS: Yes, we did look at -- we
12 did not do an analysis of death due to C. diff
13 because there really were no differences. But we
14 didn't predefine an attributable mortality
15 definition, so to speak, so it's hard for us to
16 tell you that.

17 However, what we did do, as you saw on the
18 safety side, is we allowed for the physicians to
19 report those C. diff infections that they
20 considered were serious.

21 Remember, serious could mean they could lead
22 to hospitalization, they were considered life

1 threatening, and there were differences, 48 versus
2 23 patients in the safety side of patients who had
3 serious CDI infections, even if there was no
4 difference from deaths.

5 As Dr. Guris mentioned just earlier, we also
6 saw a reduction in 30-day readmissions as well
7 following that. So from the hardest event points,
8 which is obviously mortality, there is no
9 difference, and I think it's a very fair comment
10 that you're raising there.

11 But when you look at the totality of the
12 data, we do believe not only are we impacting on
13 CDI recurrence, but we're also impacting on
14 significant CDI recurrence that would matter to the
15 patient in how they feel, function, and survive.

16 DR. BADEN: Dr. Green?

17 DR. GREEN: Thank you. Mike Green,
18 Pittsburgh. Both my questions, or several
19 questions really, I think now follow on to the
20 committee's. The first is really an extrapolation
21 and an ongoing exploration of the last topic. So I
22 think it's clear that sometimes biologics may not

1 prevent but may modify, and I want to just explore
2 this a little bit more.

3 So Dr. Baden was asking about differences in
4 death associated with recurrence, and you also
5 shared with us rehospitalizations. But some
6 patients with C. difficile stay in the hospital
7 despite that they were there for a different
8 reason, they stay for other reasons.

9 So just exploring further amongst patients
10 who have a recurrence in the treated versus placebo
11 group, if you saw a difference in progression to
12 ICU, progression to colectomy associated with the
13 recurrence, I think you just answered the question
14 with death, and then I think you said separately
15 the question of rehospitalization and those who get
16 cured and go home. So it's really sort of looking
17 at those different issues.

18 DR. KARTSONIS: Sure. So we did carefully
19 look at all the C. diff recurrences to see were
20 there any differences, particularly among the
21 patients who got C. diff in terms of the severity
22 of the disease.

1 I mentioned earlier the FMT differences that
2 were noted. We also looked at the maximum number
3 of loose stools. We looked at time to resolution
4 of their C. diff infection. In fact, we did see a
5 numerically higher percentage of patients resolve
6 their C. diff infection if they had developed in
7 the setting of bezlotoxumab as opposed to developed
8 a placebo.

9 If you could put the slide up, please. So
10 this is a slide that shows the data from the 335
11 patients in the placebo and bezlotoxumab group who
12 had recurrent CDI episodes. And it looks at the
13 severity of the episodes that did occur.

14 The median number of loose stools did not
15 differ, but you can see the maximum number of loose
16 stools were higher in a placebo group versus BEZLO.

17 As I mentioned, the time to resolution of
18 the new episode resolved within 2 days in 59
19 percent of the patients on BEZLO as opposed to 48
20 percent of the patients on placebo. There were no
21 differences necessarily, so slightly higher within
22 placebo with regard to having severe CDI.

1 Another way to look at this would be to look
2 at the length of stay the patients had. You
3 mentioned their length of stay. And we did do a
4 separate analysis as well. And if it's okay, I'll
5 call Dr. Guris up to speak to the length of stay
6 analysis that we performed.

7 DR. GUIB: Slide up, please. So this is a
8 forest plot by risk groups. And here what we
9 calculated is the length of stay, hospital stay
10 throughout the 84-day period. This includes the
11 initial hospital stay that the patients had as
12 well.

13 As you can see, overall and in each risk
14 group, there is a reduction in hospital stay.
15 Overall, it is 2 days. That's the first column
16 that you see where it was 14.2 percent in the
17 placebo -- 2 days in the placebo group versus 12
18 days in the BEZLO group. So there's two days'
19 reduction in overall length of stay in the BEZLO
20 group compared to placebo.

21 DR. KARTSONIS: Thank you. Just to add to
22 the last part about the colectomy, we didn't have a

1 lot of patients who went on to develop or need a
2 colectomy. It was really just a handful and there
3 were no differences in those groups.

4 DR. GREEN: I have one more. And then my
5 next question is in response to a comment that Dr.
6 Wilcox made about the potential of BEZLO to impact
7 secondary spread of disease. And I'm not 100
8 percent certain whether that would or would not
9 happen. So you are impacting the toxin, you're not
10 eradicating the recurrent organism.

11 On the other hand, it might be more easily
12 spread if you have diarrhea versus if you simply
13 have colonization without diarrhea. And getting at
14 these data would have probably been challenging
15 because you probably would have had to ask
16 hospitals for their nosocomial C. diff rates
17 affiliated with patients in your study. But I
18 wondered if you tried in any effort to get at that
19 inference that Dr. Wilcox made.

20 DR. KARTSONIS: We did not. We didn't
21 really have a mechanism to do so, so we didn't ask
22 any hospitals if they were centers of excellence

1 for C. diff or anything of that sort. So we don't
2 have that information necessarily with regard to
3 that.

4 I will tell you the one thing we did look at
5 is we did look at did we have any impact on
6 colonization. And we did that as part of an
7 extension phase of our study that followed patients
8 out to a year, and there really were no differences
9 in terms of colonization over time.

10 But that may not necessarily be a marker
11 because, you know you would imagine that to spread,
12 you'd probably have to do so in a setting of
13 diarrhea or a loose stool. So we don't have that
14 information to be able to share with you today.

15 DR. BADEN: As it is now 10:46, I know we
16 all have many more questions, including myself, but
17 I think we should take our break. We'll have the
18 FDA presentation and we will have time to delve in
19 deeper to many of the issues that we still need to
20 understand. So we'll take a break for 15 minutes.

21 While we take the 15-minute break, panel
22 members please remember there should be no

1 discussion of the meeting topic during the break
2 amongst yourselves or with any other member of the
3 audience. We will resume promptly at 11:00 a.m.

4 (Whereupon, at 10:48 a.m., a recess was
5 taken.)

6 DR. BADEN: It is now 11:03. We will resume
7 the next session. There are still many of the
8 panel members who have mentioned that they have
9 questions, clarifying questions for the sponsor. I
10 encourage panel members to continue to let Lauren
11 and myself know if you have questions and we will
12 make sure all questions are addressed.

13 But in the process I want to make sure we
14 have a chance to get through the meat of the agenda
15 so that we have all of the information on the table
16 to be discussing. So we'll proceed to the FDA's
17 presentations, clarifications with the agency,
18 depending on the time, more questions or more
19 likely have lunch. And then, after lunch, we will
20 resume further discussion.

21 So we'll now proceed with the agency's
22 presentations. And I think Dr. Dixon will be

1 presenting first.

2 **FDA Presentation - Cheryl Dixon**

3 DR. DIXON: Yes. Good morning. I am Cheryl
4 Dixon, the statistical reviewer for the
5 bezlotoxumab BLA submission. I will be presenting
6 the division's assessment of the clinical efficacy
7 of bezlotoxumab for the prevention of Clostridium
8 difficile infection recurrence.

9 As you will see from my presentation, we are
10 in general agreement with most of the results as
11 presented by the applicant earlier this morning,
12 however we differ in the ability to interpret those
13 results and the final conclusions drawn.

14 In my presentation, I will be discussing the
15 regulatory history of the clinical development
16 program. I will provide an overview of the design
17 of the phase 3 trials, P001 and P002, focusing on
18 the endpoints used to assess the efficacy of
19 bezlotoxumab.

20 I will then briefly summarize patient
21 disposition and patient demographics and
22 characteristics, followed by a discussion of the

1 efficacy results for the main endpoints and then
2 with a summary and conclusions.

3 The IND for which bezlotoxumab was studied
4 under was submitted in November of 2005. The
5 phase 2 trials were conducted between 2005 and
6 2008. The first phase 2 trial, P018, was designed
7 to evaluate the efficacy and safety of actoxumab,
8 the antitoxin A antibody.

9 This trial was stopped early when emerging
10 preclinical data suggested the need for inclusion
11 of antibodies directed against toxin B as well in
12 the monoclonal antibody regimen.

13 P017 was then designed to evaluate the
14 efficacy and safety of the combined monoclonal
15 antibodies actoxumab plus bezlotoxumab. This trial
16 was considered the proof of concept trial for the
17 clinical development of the combination monoclonal
18 antibody regimen. As the focus of the clinical
19 development program became the combination
20 monoclonal antibody regimen, no phase 2 trials
21 which evaluated bezlotoxumab alone were conducted.

22 In October of 2009, an end-of-phase-2

1 meeting was held with the applicant. At this
2 meeting, the applicant proposed to conduct two
3 pivotal phase 3 trials of identical design to
4 evaluate the combination of actoxumab plus
5 bezlotoxumab administered in combination with
6 standard of care antibiotics in patients with CDI.

7 The proposed primary endpoint was CDI
8 recurrence during the study period, where CDI
9 recurrence was defined as the development of a new
10 episode of diarrhea associated with a positive
11 stool test for *C. difficile* following clinical cure
12 of the initial CDI episode.

13 The division concurred with the definition
14 of CDI recurrence, but indicated that the CDI
15 recurrence rate should be based on all randomized
16 patients and not based on the subset of clinical
17 cures.

18 The division also advised that a 4-arm
19 factorial design, which included actoxumab alone,
20 bezlotoxumab alone, the combination of actoxumab
21 plus bezlotoxumab, and placebo be implemented in
22 one of the phase 3 trials in order to address the

1 combination drug rule.

2 In July of 2010, a special protocol
3 assessment was requested for P001. The submitted
4 protocol incorporated the factorial design and the
5 calculation of the CDI recurrence rate as
6 recommended at the end of phase 2 meeting and also
7 incorporated an interim analysis to allow for
8 dropping of an individual monoclonal antibody arm
9 if the results were favorable to do so. In
10 December of 2010, an SPA agreement for P001 was
11 made.

12 The protocol for P002 was reviewed in 2012.
13 At this time, after further evaluation by the
14 statistical review team, it became apparent that
15 there were scientific concerns with the primary
16 endpoint of CDI recurrence as defined.

17 The CDI recurrence endpoint essentially
18 treats subjects who failed treatment of the initial
19 CDI episode as not having a recurrence since they
20 are included in the denominator of the recurrence
21 rate. This does not seem intuitively appropriate
22 since the clinical failures cannot be evaluated for

1 recurrence as one has to be cured first in order to
2 develop recurrence.

3 The ability to interpret this endpoint is of
4 most concern, however, if there is an imbalance in
5 the proportion of subjects with initial clinical
6 cure between the treatment groups, particularly if
7 the monoclonal antibody group has a lower initial
8 clinical cure rate than the placebo group, because
9 this results in a smaller number of subjects in the
10 monoclonal antibody arm that can potentially
11 develop recurrence, but a larger number of subjects
12 who by default are considered as not having a
13 recurrence in the analysis.

14 Given these concerns, the more relevant
15 endpoint for assessing the efficacy of the
16 monoclonal antibody regimen would be global cure,
17 which is defined as clinical cure of the initial
18 CDI episode and no CDI recurrence. Therefore, it
19 was requested that the primary endpoint for P002 be
20 changed to global cure.

21 The applicant did not expect the monoclonal
22 antibodies to have an impact on clinical cure and

1 indicated their preference for both trials to have
2 the same primary endpoint. The division further
3 pointed out that if there was no difference in
4 clinical cure, then the difference between the
5 treatment arms for global cure should be similar to
6 the difference between treatment arms for the
7 recurrence endpoint.

8 The applicant still maintained that CDI
9 recurrence was the appropriate primary endpoint for
10 P002, in part that the power of the trial for
11 achieving success was not planned based on global
12 cure. They proposed to conduct a pooled analysis
13 of the two phase 3 trials in order to address this
14 concern.

15 In the end, the division acknowledged the
16 applicant's intent to retain CDI recurrence as a
17 primary endpoint in P002, again reiterated our
18 concerns with this endpoint, and disagreed with the
19 proposed pooled analysis for assessing global cure
20 just to ensure substantial power.

21 As we would want confirmatory evidence from
22 separate trials the division intended to base our

1 assessment of global cure, as well as all efficacy
2 endpoints, on the analyses from the trials
3 individually.

4 I will try to illustrate our concerns with
5 the choice of endpoint a little further in the next
6 few slides. The intended role of the monoclonal
7 antibody is for the prevention of CDI recurrence.
8 The applicant believed, based on the assumed
9 activity of the monoclonal antibody, that it was
10 best to treat the patient with the monoclonal
11 antibody while the patient was receiving standard
12 of care treatment for the initial CDI episode
13 rather than waiting until treatment with standard
14 of care was complete and the patient was considered
15 successfully treated.

16 Typically, the recurrence rate would be the
17 number of patients with a recurrence divided by the
18 number of patients with clinical cure. However,
19 due to the study design, patients with clinical
20 cure is a post-randomization and post-treatment
21 subgroup. Therefore, the recurrence rate was
22 defined in the protocol as the number of patients

1 with a recurrence divided by the number of patients
2 treated regardless of initial clinical response.

3 However, there are concerns with this
4 definition which may best be seen when looking at
5 the complement of the recurrence rate in which
6 subjects who maintained clinical response and did
7 not have a recurrence are grouped with those who
8 were clinical failures of the initial CDI episode.
9 This intuitively does not seem appropriate.

10 Additionally, the clinical failures are not
11 evaluated for recurrence but are treated by default
12 as not having a recurrence. So a larger number of
13 clinical failures will lead to an underestimate of
14 the actual recurrence rate. This would be of most
15 concern in the assessment of the monoclonal
16 antibody if the monoclonal antibody group had more
17 clinical failures than the placebo group.

18 Therefore, the more relevant endpoint for
19 assessing the efficacy of the monoclonal antibody
20 would be global cure in which those who are not
21 clinical cures are grouped with those who had
22 recurrence and are more appropriately treated as

1 failures in the analysis. The global cure endpoint
2 will capture the full effect of the monoclonal
3 antibody. In other words, its effect, if any, on
4 initial cure as well as the effect on recurrence.

5 The next two slides include very simplistic
6 hypothetical examples to support our preference of
7 the global cure endpoint. In this hypothetical
8 example, no difference in the initial clinical cure
9 is assumed, as was the assumption by the applicant
10 for the monoclonal antibody. In both arms, there
11 are 100 total patients of which 80 were clinical
12 cures. In arm 1, 10 of the 80 developed
13 recurrence, whereas in arm 2, 25 of the 80
14 developed recurrence.

15 Therefore, the recurrence rate, based on the
16 protocol definition, would be 10 percent for arm 1
17 and 25 percent for arm 2, with an absolute
18 difference of 15 percent. The global cure rate
19 would be 70 percent for arm 1 and 55 percent for
20 arm 2, and also has an absolute difference of 15
21 percent. Therefore, if there was no difference in
22 initial clinical cure, then the global cure

1 endpoint would allow for the same assessment of
2 treatment effect as the recurrence endpoint.

3 In this hypothetical example, it is assumed
4 that there is a difference in the initial clinical
5 cure between arms and the clinical cure rate for
6 arm 1 is lower than that for arm 2. The recurrence
7 rate is assumed to be the same as was observed in
8 the previous example, with arm 1 having a lower
9 recurrence rate than arm 2.

10 However, when looking at global cure in this
11 example, there is no difference between the arms
12 observed. So unless it can be proven that the
13 differences observed for initial clinical cure was
14 not due to any effect of treatment but solely a
15 random occurrence, then treatment effect would be
16 most appropriately assessed by the global cure
17 endpoint, as it captures the effect on initial cure
18 as well as recurrence, whereas just considering
19 recurrence ignores the possible effect treatment
20 may have on clinical cure.

21 I will now return to a discussion of the
22 phase 3 trials. Both trials were randomized,

1 multi-center, double-blind, placebo-controlled
2 trials conducted in subjects 18 years or older who
3 were receiving standard of care antibiotic
4 treatment for an episode of CDI.

5 In P001, subjects were randomized in a 1 to
6 1 to 1 to 1 ratio to receive a single infusion of
7 actoxumab, bezlotoxumab, the combination, or
8 placebo. In P002, subjects were randomized in a
9 1 to 1 to 1 ratio to receive a single infusion of
10 bezlotoxumab, actoxumab plus bezlotoxumab, or
11 placebo.

12 The infusion could occur at any time during
13 treatment with standard of care, and the patient
14 did not need to be experiencing diarrhea at the
15 time they entered the trial. Randomization was
16 stratified by oral standard of care therapy, which
17 included metronidazole, vancomycin or fidaxomicin,
18 and by hospitalization status, which was inpatient
19 or outpatient.

20 The design for P001 also included an interim
21 analysis which allowed for the halting of further
22 enrollment into one or both of the individual

1 monoclonal antibody treatment groups if there was
2 sufficient evidence of superiority of the
3 combination over the individual monoclonal
4 antibody.

5 Based on the results of the interim
6 analysis, which showed low efficacy, an observed
7 increase in the number of deaths and serious
8 adverse events in the actoxumab arm compared to
9 placebo, enrollment in the actoxumab arm was
10 stopped following the recommendation of an
11 independent data monitoring committee. Enrollment
12 in the remaining three treatment groups continued
13 until trial completion.

14 The protocol-specified primary endpoint was
15 CDI recurrence. As previously mentioned, CDI
16 recurrence was defined as the development of a new
17 episode of diarrhea associated with a positive
18 stool test for toxigenic *C. difficile* following
19 clinical cure of the baseline CDI episode.

20 Clinical cure of the baseline CDI episode
21 required the subject to have received standard of
22 care treatment for less than or equal to 14 days,

1 and not have diarrhea on the 2 days immediately
2 following the last day of standard of care
3 antibiotic treatment.

4 Global cure was a secondary endpoint and was
5 defined as clinical cure of the baseline episode
6 and no CDI recurrence. Clinical cure as an
7 endpoint on its own was considered an exploratory
8 endpoint.

9 The primary analysis population was the full
10 analysis set or FAS. The FAS population was a
11 subset of all randomized subjects excluding those
12 who did not receive an infusion of study
13 medication, did not have a positive stool test for
14 toxigenic *C. difficile* at study entry, or did not
15 receive a protocol defined standard of care therapy
16 within a one day window of the infusion.

17 Additionally, in P001, subjects from a
18 single investigative site found by the applicant to
19 have serious good clinical practice non-compliance
20 issues were excluded from the FAS.

21 The primary analysis of the efficacy
22 endpoints was a comparison of treatment groups in

1 the proportion of subjects with CDI recurrence,
2 global cure, or clinical cure using the FAS
3 population. Adjusted differences in the rate and
4 corresponding 95 percent confidence interval
5 stratified by oral standard of care therapy and
6 hospitalization status were also calculated.

7 To control type 1 error rate due to multiple
8 treatment comparisons, a sequential testing
9 approach was used. In both studies, the order of
10 the testing was the combined monoclonal antibody
11 versus placebo comparison and, if significant,
12 followed by the bezlotoxumab versus placebo
13 comparison.

14 In addition, P001 adjusted the alpha level
15 to control for the interim analysis as well as the
16 second primary objective to compare the combined
17 monoclonal antibody arm to each of the individual
18 monoclonal antibody arms.

19 As previously indicated, the division's
20 assessment of efficacy is based on the results of
21 the individual studies. Therefore, no efficacy
22 results of the studies pooled will be presented.

1 Approximately 400 subjects per treatment arm
2 were randomized into the trials with the exception
3 of the actoxumab-alone arm of P001 for which
4 enrollment was halted after the interim analysis.
5 Overall, 96 percent of the randomized patients in
6 both trials were included in the FAS, and most of
7 the patients excluded from the FAS were due to not
8 receiving study infusion.

9 Demographic and baseline characteristics of
10 the FAS population were generally balanced among
11 treatment groups in both trials. Overall, the mean
12 age of patients was 62 years in P001 and 64 years
13 in P002. Approximately 56 to 57 percent were
14 female, and the majority of the subjects were
15 white. A similar proportion of patients received
16 metronidazole or vancomycin as their oral standard
17 of care, and only 3 percent received fidaxomicin as
18 their standard of care.

19 Approximately 53 percent of the patients in
20 P001 and 41 percent in P002 were enrolled at sites
21 from the United States or Canada, and a slightly
22 larger percentage of patients from Asian sites were

1 enrolled in P001 than P002.

2 The majority, 67 to 69 percent, of the
3 patients were hospitalized at the time of
4 enrollment. Only approximately 34 percent of the
5 patients had a prior history of CDI ever, although
6 most of those events had been in the 6 months prior
7 to enrollment.

8 A hyper-virulent strain of *C. difficile*,
9 defined as ribotypes 027, 078, or 244, was detected
10 in approximately 12 percent of patients in P001 and
11 14 percent of the patients in P002 overall.

12 However, in P002, slightly more placebo patients
13 had a hyper-virulent strain of *C. difficile* as
14 compared to the other two treatment arms.

15 The median duration of standard of care
16 prior to the infusion was 3 days in both studies
17 and ranged from 14 days before study infusion to
18 the day after study infusion was received.

19 Overall, 28 percent of the patients in P001
20 experienced diarrhea on the day of the study
21 infusion.

22 While in P002 23 percent of the patients

1 overall experienced diarrhea on the day of the
2 study infusion, the bezlotoxumab arm had a slightly
3 lower percentage of patients experiencing diarrhea
4 on the day of infusion, 18 percent as compared to
5 26 percent in the other 2 arms.

6 Given the median duration of standard of
7 care prior to the infusion was 3 days, and
8 typically antibiotic treatment is having an effect
9 by then, the fairly large percentage of patients
10 not experiencing diarrhea on the day of study
11 infusion would be anticipated.

12 This table presents the results for initial
13 cure, CDI recurrence, and global cure in the FAS
14 population of P001. Since enrollment in the
15 actoxumab arm in P001 was halted following the
16 interim analysis, these results have not been
17 presented. Please note that I have presented
18 two-sided rather than one-sided p-values for ease
19 in interpretation due to situations where the
20 placebo arm was better than the monoclonal antibody
21 arm.

22 In P001, there was a significantly lower

1 proportion of subjects with CDI recurrence in both
2 the combined monoclonal antibody arm and the
3 bezlotoxumab arm as compared to placebo. The
4 adjusted differences in CDI recurrence were at
5 least 10 percent in favor of the monoclonal
6 antibody arms as compared to placebo. A slightly
7 lower proportion of subjects had CDI recurrence in
8 the combination monoclonal antibody group as
9 compared to bezlotoxumab, but the difference was
10 not statistically significant.

11 Clinical cure of the initial CDI episode was
12 lower for both the monoclonal antibody, which was
13 significantly lower, and the bezlotoxumab, which
14 was numerically lower, as compared to placebo. Due
15 to this negative imbalance in initial clinical
16 cure, the interpretation of the CDI recurrence
17 endpoint is complicated.

18 Thus, global cure, which captures the
19 overall effect of the treatment, would be the more
20 appropriate endpoint to consider. Although the
21 proportions of subjects with global cure were
22 numerically in favor of the combined monoclonal

1 antibody group and bezlotoxumab in comparison to
2 placebo, the differences were not statistically
3 significant.

4 This table presents the results for P002.
5 In P002, the results for CDI recurrence were
6 similar to those seen in P001. There was a
7 significantly lower proportion of subjects with CDI
8 recurrence in both the combined monoclonal antibody
9 group and the bezlotoxumab group as compared to
10 placebo. And the adjusted differences in CDI
11 recurrence were approximately 10 percent in favor
12 of the monoclonal antibody arms compared to
13 placebo.

14 A slightly lower proportion of subjects had
15 CDI recurrence in the combined monoclonal antibody
16 group as compared to bezlotoxumab, but again, the
17 difference was not statistically significant.

18 As seen in P001, clinical cure of the
19 initial CDI episode was numerically lower for the
20 combined monoclonal antibody group compared to
21 placebo. However, clinical cure was numerically
22 higher for the bezlotoxumab as compared to placebo.

1 Neither of these comparisons were statistically
2 significant.

3 Although the proportion of subjects with
4 global cure was numerically in favor of the
5 combined monoclonal antibody group compared to
6 placebo, the adjusted difference of 5.2 percent was
7 not statistically significant. The proportion of
8 subjects with global cure in the bezlotoxumab group
9 was significantly higher than placebo with an
10 adjusted difference of 14.6 percent.

11 However, the significance of this difference
12 should be interpreted with caution given the
13 predefined testing strategy in which the combined
14 monoclonal antibody group versus placebo comparison
15 was to be tested first.

16 Given the results shown in the previous
17 slides, there is a concern that bezlotoxumab alone
18 and in combination with actoxumab may have a
19 negative effect on initial clinical cure.
20 Therefore, in order to explain the unanticipated
21 differences observed for clinical cure, the reasons
22 for failure to achieve clinical cure were further

1 investigated.

2 In both trials, the most common reasons for
3 failure were evidence of diarrhea during at least 1
4 of 2 days after standard of care was completed or
5 the standard of care was received for greater than
6 14 days. Most of the subjects who received greater
7 than 14 days of standard of care did so because of
8 continued loose stools, although some subjects
9 received continued standard of care even though
10 their diarrhea had resolved.

11 The proportion of subjects who had missing
12 stool information or discontinued prior to the end
13 of standard of care was generally balanced across
14 the treatment groups. Therefore, the difference in
15 clinical cure rates observed can primarily be
16 attributed to continued loose stools or evidence of
17 diarrhea, which was higher for the combined
18 monoclonal antibody group in both trials, and for
19 the bezlotoxumab group in P001 as compared to
20 placebo.

21 Various sensitivity analyses were conducted
22 by the applicant and the division. The results of

1 most of these analyses were fairly consistent to
2 the results observed for the primary analysis.

3 In the primary analysis, the assessment of
4 CDI recurrence was based on the last available
5 information for a subject. Therefore, subjects
6 with incomplete information to assess recurrence,
7 such as those having a new episode of diarrhea but
8 for whom a stool sample was not collected for toxin
9 testing, those who died prior to week 12, or those
10 whose last stool information was collected prior to
11 day 80, were treated as not having a recurrence.

12 Treating incomplete information in this way
13 could lead to an underestimate of the CDI
14 recurrence rate. Additionally, it was noted that
15 some subjects received a concomitant medication or
16 procedure potentially useful in the treatment of
17 CDI during the follow-up period, which can confound
18 the assessment of recurrence.

19 Therefore, one of the sensitivity analyses
20 conducted by the division imputed subjects with
21 incomplete information on their stool or as well as
22 those who received a concomitant medication or

1 procedure potentially useful in the treatment of
2 CDI during the follow-up period as a recurrence or
3 failure.

4 The results of the sensitivity analysis for
5 P001 are presented in this slide. As you can see
6 from the bottom of this table, a similar proportion
7 of subjects did not have a stool sample of a new
8 episode of diarrhea collected for toxin testing,
9 died before week 12, or did not have stool
10 information past day 80.

11 A slightly higher proportion of placebo
12 subjects received an active concomitant medication
13 or procedure for CDI during follow-up as compared
14 to the combined monoclonal antibody group or the
15 bezlotoxumab group. Thus, a slightly higher
16 proportion of placebo subjects were imputed as a
17 CDI recurrence in this sensitivity analysis.

18 For P001, the overall conclusions are the
19 same based on the sensitivity analysis as the
20 primary analysis, although with the sensitivity
21 analysis a slightly larger treatment difference for
22 CDI recurrence and for global cure is observed.

1 The results of the sensitivity analysis for
2 P002 are presented in this slide. As you can see
3 from the bottom of the table, there is an imbalance
4 between the monoclonal antibody groups and placebo
5 in the number of subjects who did not have a stool
6 sample of a new episode of diarrhea collected for
7 toxin testing. There was also a slightly larger
8 proportion of bezlotoxumab subjects who received an
9 active concomitant medication or procedure for CDI
10 during the follow-up.

11 Thus, the overall imbalance impacts the
12 conclusions drawn for the CDI recurrence endpoint
13 in which bezlotoxumab versus placebo comparison is
14 no longer significant. Although the difference in
15 global cure is statistically significant for the
16 bezlotoxumab versus placebo comparison, but again
17 should be interpreted as so with caution, the
18 difference is less than that observed for the
19 primary analysis and is driven as much by the
20 difference that was observed in clinical cure of
21 the initial CDI episode as the difference in CDI
22 recurrence.

1 Numerous subgroup analyses were also
2 conducted. In general, the results of most
3 subgroups were consistent and the treatment
4 differences trended in the same direction as the
5 overall population. Exceptioned were those of
6 gender and age where the treatment differences of
7 CDI recurrence and global cure observed for males
8 and for subjects less than 65 were not as large as
9 those observed for females and for those 65 years
10 or older respectively.

11 In summary, there appears to be a decrease
12 in CDI recurrence with the use of bezlotoxumab.
13 However, the CDI recurrence endpoint is difficult
14 to interpret since subjects without clinical cure
15 of the initial CDI episode are treated as not
16 having a recurrence in the calculation of the
17 recurrence rate and also due to the imbalance noted
18 in the proportion of subjects with initial clinical
19 cure between treatment groups.

20 Recall that, in P001, the difference in
21 initial clinical cure was in favor of placebo
22 compared to bezlotoxumab, but in P002 the

1 difference in initial clinical cure was the
2 reverse. A difference in clinical cure was also
3 noted for the combined monoclonal antibody group
4 compared to placebo, where in both trials the
5 difference is in favor of placebo. Therefore, a
6 negative effect of bezlotoxumab on clinical cure of
7 the initial CDI episode cannot be ruled out.

8 Due to these concerns, global cure would be
9 the more relevant endpoint to assess the efficacy
10 of bezlotoxumab as it captures the overall effect
11 of the treatment. The results for global cure are
12 only significant for one of the two trials, and the
13 significance observed in P002 needs to be
14 interpreted with caution for two reasons.

15 The first is the non-significant result of
16 global cure observed for the actoxumab plus
17 bezlotoxumab arm versus placebo comparison, which
18 was to be conducted prior to the bezlotoxumab
19 versus placebo comparison based on the hierarchal
20 ordering of the prespecified testing strategy.

21 The second reason, and possibly more
22 clinically relevant, is the discordant results

1 observed for clinical cure for bezlotoxumab between
2 the two trials as I mentioned in the previous
3 slide. The results observed for the actoxumab plus
4 bezlotoxumab arm were consistent across both
5 trials, and the results for bezlotoxumab in P001
6 are more similar to these results.

7 So in conclusion, while there appears to be
8 a decrease in CDI recurrence with the use of
9 bezlotoxumab, there is concern as to whether the
10 efficacy of bezlotoxumab for the prevention of CDI
11 recurrence has been adequately demonstrated and
12 whether a negative effect of bezlotoxumab on
13 clinical cure of the initial CDI episode can be
14 ruled out.

15 I will now turn the presentation over to Dr.
16 Hiwot Hiruy, who will be presenting the division's
17 assessment of the clinical safety of bezlotoxumab.

18 **FDA Presentation - Hiwot Hiruy**

19 DR. HIRUY: Thank you, Dr. Dixon. My name
20 is Hiwot Hiruy. I will present the clinical safety
21 review for bezlotoxumab. I'll start the safety
22 presentation with methodology used for safety

1 analysis then present the overall exposure to
2 bezlotoxumab, death, serious adverse events and
3 treatment emergent adverse events that occurred in
4 the safety population. I will also discuss our
5 analysis of infusion related adverse reactions, and
6 finish with results of some of our subgroup
7 analyses.

8 Before starting my presentation I want to
9 cover the definitions of treatment-emergent adverse
10 events and serious adverse events used for the
11 analysis. Treatment-emergent adverse event is
12 defined as any adverse event that occurred during
13 or after infusion of the study drug. Definition of
14 serious adverse event included adverse event terms
15 per ICH-E2A and are listed below the serious
16 adverse event bullet point there.

17 In addition, the sponsor included two
18 additional adverse event terms, adverse events that
19 result in cancer, and adverse events associated
20 with overdose in the serious adverse event
21 reporting. The sponsor's definition of serious
22 adverse events were used in the safety analysis.

1 Because the design of the two pivotal
2 studies P001 and P002 were similar, including
3 adverse event reporting schema, data for the two
4 studies were pooled together. In both studies,
5 treatment-emergent adverse events were reported for
6 the first 4 weeks of the studies and serious
7 adverse events were reported throughout the
8 12 weeks of the study period.

9 The two studies, however, did have some
10 differences. Study P001 followed an adaptive
11 design with 4 arms; BEZLO alone, ACTO alone,
12 combination arm, and the placebo arm with planned
13 interim analysis. The actoxumab-only arm was
14 dropped after the interim analysis and is not
15 included in the safety population.

16 Study P002, on the other hand, was designed
17 with 3 study arms, BEZLO alone, combination arm,
18 and placebo arm, and had an extension cohort of 300
19 subjects that were followed for additional 9 months
20 beyond the 12-week study period.

21 This diagram just illustrates that the arms
22 that received similar study infusions were pooled

1 together for the safety population. For example,
2 data for the subjects that received bezlotoxumab in
3 study P001 were combined with data for the subjects
4 that received bezlotoxumab in study P002.

5 The 4 study arms marked by the red boxes
6 made up the safety population. Any subjects that
7 received partial or full infusion of the study
8 drugs was included in the safety population. The
9 placebo arms for each of the studies were combined
10 together to make up the comparator arm. As
11 mentioned earlier, the fourth arm in P001, denoted
12 by the gray box in the diagram, the actoxumab arm,
13 is not included in the safety population.

14 Looking at the overall exposure to
15 bezlotoxumab, a total of 1790 subjects were exposed
16 to bezlotoxumab alone or in combination with
17 actoxumab. Of these, 816 received BEZLO alone, and
18 974 received BEZLO in combination with actoxumab.
19 About 126 of these subjects were healthy volunteers
20 participating in phase 1 studies, and the remaining
21 were subjects in phase 2 and 3 trials.

22 Of note, with exception of 30 subjects in

1 one phase 1 study who received 2 doses of BEZLO
2 infusion at 10 milligram per kilogram, the
3 remaining 1760 subjects received BEZLO as a single
4 10 milligram per kilogram of body weight infusion.
5 Those in the ACTO plus BEZLO, the combination arm,
6 received additional 10 milligram per kilogram of
7 the actoxumab infusion.

8 Looking at the mortality rate in the safety
9 population, a total of 56 subjects died in the
10 BEZLO arm with a mortality rate of 7.1 percent in
11 the BEZLO arm. Fifty-one subjects died in the
12 combination arm with a mortality rate of 6.6
13 percent. And 59 subjects died in the placebo arm
14 with a mortality rate of 7.5 percent over the
15 12-week study period.

16 The any BEZLO column included in this table
17 includes subjects that received bezlotoxumab either
18 alone or in combination with actoxumab. From that
19 group, 107 subjects who received any BEZLO died
20 with a total mortality rate of 6.8 percent.
21 Overall, there was no major imbalance in the
22 mortality rate among the three study arms.

1 I also included in the last row the deaths
2 that occurred in the extension arm of study P002.
3 In addition to the deaths that I reported, there
4 were additional 28 deaths in study P001 in the
5 actoxumab arm, with a mortality rate of 11.9
6 percent, which was significantly higher than the
7 other study arms. As mentioned earlier, the
8 actoxumab alone arm is not included in the safety
9 population.

10 Looking at the serious adverse events, 29.4
11 percent of subjects in the BEZLO arm, 27.3 percent
12 of subjects in the combination arm, and 32.7
13 subjects in the placebo arm experienced at least
14 one serious adverse event.

15 Slightly more subjects in the placebo arm
16 experienced serious adverse events but there was no
17 major imbalance in the proportion of subjects that
18 experienced serious adverse events among the three
19 treatment arms.

20 The infection, and infestation, and
21 gastrointestinal system organ class accounted for
22 the majority of serious adverse events reported.

1 Cardiac failure, diarrhea, and abdominal pain
2 occurred more frequently in the BEZLO arm compared
3 to placebo.

4 Looking at treatment-emergent adverse
5 events, 61.7 percent of subjects in the BEZLO arm,
6 58.6 percent of subjects in combination arm, and
7 61.2 of subjects in the placebo arm experienced at
8 least 1 treatment-emergent adverse event.

9 Most common treatment adverse event in the
10 BEZLO arm was nausea followed by diarrhea, pyrexia,
11 headache and vomiting. Again, there was no
12 imbalance in the proportion of subjects that
13 experienced treatment-emergent adverse events among
14 the 3 study arms.

15 Since bezlotoxumab is an immunoglobulin, we
16 looked at possible infusion-related adverse
17 reactions. To do so, we first looked broadly at
18 all the treatment-emergent adverse events within
19 the first 24 hours after infusion, which included
20 day 1 and day 2 of the study. We then looked for
21 combination of sign and symptoms involving two or
22 more organ systems that may be attributed to

1 infusion related reactions.

2 Infusion-related reactions search criteria
3 was adapted from Sampson's criteria and included 2
4 or more sign and symptoms for mucocutaneous
5 symptoms, respiratory, cardiac, gastrointestinal
6 and any general sign and symptoms including
7 pyrexia, diaphoresis, chills, fatigue and asthenia.
8 Also, a reduction in systolic blood pressure to
9 less than 90 millimeters of mercury or drop in
10 systolic blood pressure by more than 30 percent was
11 considered sign and symptom of infusion-related
12 reaction.

13 Overall, 18.8 percent of subjects in the
14 BEZLO arm, 15.4 of subjects in the combination arm,
15 and 14.6 of subjects in the placebo arm experienced
16 at least 1 treatment-emergent adverse event during
17 the first 2 days of the study.

18 But looking specifically at the combination
19 of sign and symptoms outlined earlier for infusion
20 related reactions, 4 subjects in the BEZLO arm
21 warranted an additional look. One subject
22 developed ventricular tachycardia 30 minutes into

1 the infusion and the sign and symptoms necessitated
2 permanent discontinuation of the infusion. The
3 details of these subjects are presented in the next
4 couple of slides.

5 Additionally, 2 subjects were reported to
6 have hypotension during infusion, but neither of
7 these patients had systolic blood pressure less
8 than 90 or had dropped by more 30 percent. One
9 subject did have a drop in systolic blood pressure
10 by more than 30 percent from baseline at 30 minutes
11 after start of infusion and at the end of infusion.

12 The subject that had permanent
13 discontinuation of the bezlotoxumab infusion was a
14 32-year-old male with HIV/AIDS, pneumocystis
15 pneumonia, and history of hyponatremia and
16 hypokalemia, but no history of arrhythmia with
17 normal pre-infusion electrocardiogram with atrial
18 and ventricular rate of 103 beats per minute.

19 As mentioned earlier, he developed
20 ventricular tachycardia with a heart rate of 200
21 beats per minute, chills, dizziness approximately
22 36 minutes after the start of the infusion.

1 His pre-infusion vital signs showed sinus
2 tachycardia of 110 beats per minute, blood pressure
3 110/70, temperature of 38.3, respiratory rate of
4 20. Thirty minutes after the start of the
5 infusion, his vital signs showed a heart rate of
6 200, blood pressure 120/80, temperature of 38.5,
7 and respiratory rate of 20.

8 His pre-infusion labs were notable for
9 potassium of 5.3 mL equivalence per liter, low
10 calcium of 8.2 milligram per deciliter. He had
11 multiple concomitant medications, which included
12 pentamidine, potassium, pantoprazole, and
13 prednisone.

14 Shortly after the symptoms developed, the
15 bezlotoxumab infusion was discontinued and the
16 subject was treated with steroids and histamine
17 blockers intravenously. The chills and ventricular
18 tachyarrhythmia resolved within 5 minutes after
19 discontinuation of the infusion.

20 The dizziness resolved within 90 minutes.
21 The electrocardiogram performed 30 minutes after
22 discontinuation of the infusion showed atrial and

1 ventricular rate of 99 beats per minute. The
2 sponsor considered the event as infusion related.

3 Because congestive heart failure was the
4 most common serious adverse event experienced in
5 the bezlotoxumab-containing arms, we carried out a
6 subgroup analysis to evaluate whether there was a
7 difference in outcome in relation to a baseline
8 CHF. Of note, information about the stage of CHF
9 for subjects was not provided, and CHF was taken as
10 a dichotomous variable.

11 We compared the occurrence of serious
12 adverse events and death among subjects with
13 baseline CHF compared to those without baseline
14 CHF.

15 Not surprisingly, those with baseline CHF
16 experienced more serious adverse events compared to
17 those without baseline CHF, 48.9 percent versus
18 26.7 percent respectively. The proportion of death
19 was also higher for those with baseline CHF.

20 When looking at the 325 subjects with
21 baseline CHF by treatment arm, those in the BEZLO
22 arm had numerically higher number of treatment-

1 emergent adverse events, serious adverse events,
2 death compared to the placebo. Of note, the
3 baseline characteristics including the median age,
4 CHF severity, Charlson Comorbidity scores were
5 comparable among the three treatment arms.

6 Looking at the serious adverse events
7 experienced in the bezlotoxumab-treated subjects
8 with baseline CHF, infection and infestation
9 accounted for 30 percent of the serious adverse
10 events, followed by cardiac 21 percent of the
11 serious adverse events, and respiratory accounted
12 for 10 percent of serious adverse events.

13 Looking at the placebo arm, the top three
14 organ system classes that accounted for the
15 majority of serious adverse events were again
16 infection and infestation about 41 percent, cardiac
17 10 percent, and gastrointestinal is another 10
18 percent.

19 Looking at the serious adverse events that
20 occurred in more than 2 subjects in the
21 bezlotoxumab arm, cardiac failure occurred in 15
22 subjects in the BEZLO arm compared to 5 subjects in

1 the placebo arm.

2 This table summarizes briefly the causes of
3 death noted in the subjects with baseline CHF.
4 CHF, cardiac arrest and respiratory failure were
5 the top 3 causes of death in the bezlotoxumab arm.

6 We also carried out additional subgroup
7 analyses by age, sex, race, and body weight, and
8 there were no significant differences in treatment-
9 emergent adverse events, serious adverse events,
10 and deaths among the study arms.

11 In summary, 1,790 subjects have been exposed
12 to bezlotoxumab alone or in combination with
13 actoxumab. Overall, the proportion of treatment-
14 emergent adverse events, serious adverse events and
15 death were similar in the bezlotoxumab-containing
16 arms and the placebo arm.

17 There was one infusion reaction that led to
18 discontinuation of bezlotoxumab infusion. There
19 were higher number of subjects who experienced
20 congestive heart failure in bezlotoxumab containing
21 arms, 17 in the BEZLO arm, 17 in the combination
22 arm, compared to 7 in the placebo arm. There were

1 higher number of serious adverse events and death
2 in bezlotoxumab-treated subjects with baseline
3 congestive heart failure as compared to placebo.

4 This concludes the safety review
5 presentation.

6 **Clarifying Questions to the Presenters**

7 DR. BADEN: Thank you both for extensive
8 presentations and analyses of these complex
9 datasets. Are there any clarifying questions for
10 the FDA from the committee? Dr. Moore?

11 DR. MOORE: So, yes thank you. Dr. Hilton
12 and I were actually looking at page 10. That would
13 be slides 19 and 20, where the serious adverse
14 event, there was, sorry, discordance between the
15 consistency, inconsistency between the two slides
16 where the colors are off.

17 I just want to make sure that those were
18 labeled all correctly. So for example, respiratory
19 is light green, but then GI is light green in the
20 next slide. Do you know what I mean? You can't
21 make a direct comparison, so I just want to make
22 sure that those are actually labeled correctly.

1 DR. BADEN: Please use your microphone when
2 responding.

3 DR. HIRUY: Yes, you are right. The color
4 coding is not congruent in the two.

5 DR. MOORE: Thank you.

6 DR. BADEN: Dr. Goetz?

7 DR. GOETZ: Yes, I had a question about the
8 mortality data. If you look at slide 17 in the
9 safety, my understanding is this analysis looks at
10 people on ACTO and BEZLO, and BEZLO alone. So the
11 mortality -- actually, I've seen where I'm reading
12 that. We have broken those out and see the same
13 trends. I'm sorry. I misread the slide for a
14 moment.

15 DR. HIRUY: Okay.

16 DR. BADEN: Dr. Schaenman?

17 DR. SCHAENMAN: I had a question regarding
18 the efficacy analysis and I wanted to thank you for
19 including actual numbers in the breakdown, looking
20 at the slides that start with 7. Certainly, as a
21 clinician, I appreciate the focus on global cure
22 rate because I think that's what we as physicians

1 and that's what patients want, both of those good
2 things. But I also see the question of focusing
3 solely on recurrence as also having some merit.

4 I was curious in looking at these variables,
5 if it would be at all valid to look at sort of like
6 a true recurrence rate of N -- let's see, I feel
7 like, as I'm getting older, maybe I start to need
8 glasses -- N with the sub R with the denominator as
9 the clinical cure rather than big N . Would that be
10 a valid way to look solely at recurrence and
11 separating out the cure question?

12 DR. DIXON: The applicant presented those
13 results earlier this morning.

14 DR. SCHAEFMAN: But do you feel that that's
15 valid?

16 DR. DIXON: Given the design of the study,
17 since that was a post-treatment and post-randomized
18 subgroup, we felt that that was not the appropriate
19 way to look at the data.

20 DR. BADEN: Dr. Follmann, did you have a
21 clarifying question on that point?

22 DR. FOLLMANN: No, I was just going to

1 say -- I was just going agree with the FDA that
2 that's basically not comparing two fair groups
3 because they're identified based on cure, yes or
4 no. And so it's not, in my mind, a very good
5 analysis. It destroys randomization.

6 DR. BADEN: Dr. Green?

7 DR. GREEN: Thank you. This is for Dr.
8 Dixon. And I think you had sort of hinted this
9 yourself. So you talked about one of the concerns
10 with looking at the BEZLO alone independent of the
11 combined BEZLO/ACTO arm as not following the
12 original statistical plan, and therefore it maybe
13 doesn't make sense.

14 But having found, through the work that the
15 ACTO alone may have a negative effect, do you think
16 from a clinical perspective -- I think you maybe
17 hinted at that -- that that's probably not
18 something that we should really focus too much on
19 and really look at the BEZLO alone independently,
20 as that is what's being considered for approval?

21 DR. DIXON: Since that's really a clinical
22 question, I'll defer to the clinical colleagues to

1 answer that part of the question.

2 DR. MISHRA: Sorry, can you clarify your
3 question?

4 DR. GREEN: Yes. Again, so one of the
5 rationale in Dr. Dixon's statistical presentation
6 to us for downplaying a benefit in a study where
7 BEZLO alone had a benefit but the combined didn't
8 have a benefit, or had a lesser benefit, was that
9 the original design was look at the combination and
10 then look at the product individually.

11 But we know that as they went through the
12 evolution of their evaluation of these, both
13 products in the combination, that it looked like
14 ACTO alone may have had -- well, it was stopped
15 because it appeared to have a negative impact, at
16 least I think, on clinical cure.

17 So knowing that, is there still a need to
18 sort of follow their original pathway when it looks
19 like a premise was wrong, that is to say that ACTO
20 alone may have been bad, and therefore the
21 combination potentially could be worse than an
22 individual drug? Or biologic actually.

1 DR. MISHRA: Right. I mean, I can't speak
2 to whether you should still follow that sort of
3 statistical pathway, but in terms of, could the
4 antitoxin A drug be sort of driving some of the
5 results that you're seeing? It's certainly
6 possible. And I think that's sort of one of the
7 underlying questions, is what is driving that?

8 Is that sort of a random occurrence that
9 this is -- that what you're seeing is all because
10 of what's happening with actoxumab? Or is this an
11 actual negative effect that you're seeing from
12 toxin B? So we don't really know.

13 DR. GREEN: Right. Again, I was just
14 raising the question because, both in the stuff we
15 received before coming here and in the oral
16 presentation, it was the rationale for considering
17 that the data didn't demonstrate as much endpoint
18 accomplishment as the sponsors might want because
19 they didn't sort of accomplish it in both. But
20 you've answered the question for me.

21 DR. BADEN: Dr. Daskalakis?

22 DR. DASKALAKIS: I just have a couple of

1 clarifying questions on the case of the ventricular
2 arrhythmia. First, the pentamidine is associated
3 with ventricular tachyarrhythmia if it's infused
4 quickly. Is there any evidence that there was a
5 use of the pentamidine fluid as flush accidentally
6 before, number one? And number two, azithromycin
7 is not listed on the patient's medications. Just
8 wondering if that's he really was not on azithro or
9 if he was.

10 DR. HIRUY: So in regards to the pentamidine
11 question. So the data I received was from the case
12 report forms, so I know that he has been on
13 pentamidine but I don't know exactly the timing of
14 infusion. He had had multiple concomitant
15 medications, so I'm pretty sure he may have been on
16 macrolide as well.

17 DR. BADEN: Do you know if it was inhaled or
18 intravenous pentamidine?

19 DR. HIRUY: It's IV. It's for treatment.
20 He's cotrimoxazole sensitive.

21 DR. COX: We could also check and see if the
22 sponsor has any additional information on that

1 case.

2 DR. KARTSONIS: Thank you, Dr. Cox. We did
3 look at this case obviously very carefully. As you
4 heard, the patient had a number of concomitant
5 underlying conditions obviously, including HIV and
6 significant immunocompromise from that as you
7 mentioned with the PCP, for which the patient was
8 getting IV pentamidine.

9 We didn't see anything unusual with regard
10 to the IV pentamidine. We'll go back and double
11 check that issue. The patient, to our knowledge,
12 we did look very closely at all their concomitant
13 medications and we do not recall the patient being
14 on a macrolide or azithromycin in particular.

15 I will, however, note several important
16 factors about this case. Besides being on
17 pentamidine and obviously being an ill patient, I
18 mean, the patient already had sinus tachycardia
19 when the patient entered into the study. And a
20 second point to keep in mind is that in particular
21 that he also had a known history, as Dr. Hiruy
22 mentioned, of electrolyte abnormalities, and

1 obviously was on both sodium and potassium
2 replacement as a result of that.

3 DR. BADEN: Dr. Follmann?

4 DR. FOLLMANN: Thanks. I wanted to sort of
5 elaborate on the comment Dr. Schaenman made. It
6 seems like the fundamental issue here is how to
7 count the cures. The FDA doesn't like to count the
8 cures as successes, which makes sense. The sponsor
9 doesn't really like to count the cures as failures
10 because this is happening during the period of time
11 when the drug should have no effect, and so why
12 should we be focusing on that endpoint then.

13 You pointed out, why don't we just throw
14 them away and that's sort of appealing except it
15 destroys randomization, so I don't think that's
16 really quite viable. But we could just ignore it
17 and say, let's start the clock at day 28 or
18 sometime like that. It's a fair starting line for
19 everyone. And then just see who has one day of
20 more than three stools, yes or no, and just count
21 as endpoint like late diarrheal success.

22 So this is a fair comparison of all the

1 groups. It gets at what the sponsor wants, which
2 is a delayed benefit of their treatment, which is
3 fair. And I think it also has the benefit
4 of -- let's suppose someone's not cured early, but
5 then is diarrhea free from day 28 until the end of
6 the study. They're counted as a success under this
7 metric, but not under any of the other ones that
8 have been proposed.

9 So I would like to see that kind of
10 analysis. To me, that sort of gets at what I think
11 is most informative and kind of fair and balances
12 the issues. And then I guess also, as a
13 sensitivity analysis on that, I would like to count
14 people as failure if you have diarrhea or die, and
15 then see. Those two analyses would be very
16 informative for me, I think.

17 DR. BADEN: So then, I guess Dr. Baden. Dr.
18 Dixon, you included in your analysis both the ACTO
19 and the BEZLO, yet this says, spinning off of Dr.
20 Green's comment, this is all about BEZLO. Why
21 shouldn't we just throw out that analysis since
22 it's about other compounds and not the one of

1 interest?

2 DR. DIXON: Because BEZLO is included in
3 that arm, it provides some additional information
4 as to what BEZLO might be contributing. You can't
5 just say that the results are driven by the ACTO
6 in that arm. They're possibly also driven by the
7 BEZLO in that arm. So that's additional BEZLO
8 information to consider.

9 DR. BADEN: Thank you. And the sponsor
10 mentioned earlier the issue of the definition of
11 clinical cure, and that if one recast that
12 definition based upon better information, they
13 provided new information that wasn't in the
14 briefing documents.

15 What is your impression of if one alters the
16 definition of clinical cure, one may make more
17 sense of these data?

18 DR. DIXON: We haven't had the chance to
19 fully review those analyses, so it's hard for me to
20 make a decision about what those results are
21 saying.

22 DR. MISHRA: I would just point out, again,

1 first of all, that's a post hoc analysis. I mean,
2 that obviously needs to be taken into account. The
3 other thing is that it was a blinded study and
4 you're still seeing sort of these differences in
5 the duration of standard of care therapy and
6 failures for patients who had diarrhea after
7 standard of care.

8 I'll tell you that we have -- we're sort of
9 in a process of looking at all these failure cases
10 and just trying to get a better handle on it. And
11 it's sort of all over the place. It's true. There
12 are some patients who, I think as the sponsor
13 noted, were very immunosuppressed, so they may have
14 a longer duration of therapy even if their diarrhea
15 had resolved.

16 But there were certainly other cases where
17 you look at where say a patient gets the standard
18 of care regimen of whatever, 10, 11 days, and the
19 infusion was given sometime during that period, and
20 then they still have lingering diarrhea for several
21 days after that. Now, in some cases, that may be
22 treated. In some cases, it wasn't treated and it

1 just sort of resolved.

2 So it's a little bit of a mixed bag in terms
3 of again how to interpret, I guess, the question of
4 the significance of these failures. And so I think
5 that's something that we're going to be taking a
6 look at more.

7 DR. BADEN: Dr. Follmann, did you have a
8 follow-up question on this theme?

9 DR. FOLLMANN: Well, yes, it was just sort
10 of the comment about a post hoc analysis. You know
11 I'm not a real big fan of post hoc analyses, but I
12 think what happened here is that, originally, there
13 was an endpoint recurrence which has problems. And
14 so they couldn't really agree on what the proper
15 endpoint should be, should it be global cure or
16 recurrence.

17 So I think the distain I have, or the
18 distaste I have for general post hoc analysis is
19 really ameliorated here because I think,
20 fundamentally, there was sort of an agreed upon
21 endpoint which I don't really like, and so I think
22 we're free and open to make our best judgment now

1 without sort of the negative, necessarily usual
2 negative consequence about a post hoc analysis.

3 DR. BADEN: Interesting. Dr. Andrews?

4 DR. ANDREWS: Thanks. I guess some of my
5 questions have been answered, but I am intrigued by
6 the possibility that you can't rule out that the
7 drug had a negative effect on cure rate as defined
8 one way. And so I'm wondering if there is any
9 plausible theory about how that could have
10 happened? Is there any reason for us to trust
11 that?

12 Can you -- this is a very naïve, very stupid
13 question probably -- but can you give the drug
14 after people are cured? Can you give it to them
15 after 12 days and stop the recurrence? Can you
16 give it to them later than right when they're in
17 the middle of needing therapy, needing treatment?

18 I like the idea, I love the idea, of looking
19 at a cure as diarrhea and death would be the not
20 cured and just put away all these questions of
21 infection versus not and how do you test it,
22 because I think those are the things that are

1 really relevant to people. And I think, given the
2 adverse events data, which is small but looks also
3 concerning, I think those kinds of patient centered
4 outcomes are really important to look at.

5 DR. MISHRA: So I'm not sure exactly what
6 the question was there, but I'll try and answer. I
7 mean, I think the question of mechanism of action
8 is still uncertain, right? So I mean, the one
9 thing that we can say is that it would sort of
10 assume that the mechanism of action of a monoclonal
11 antibody binding to the toxin wasn't going to have
12 an effect on clinical care.

13 But, early in the development program, sort
14 of the idea that the antitoxin A sort of
15 quickly -- that that would work, you quickly saw
16 the data come that it did have a negative impact.
17 So clearly, there's potentially something there
18 that we don't understand. And I think, from our
19 standpoint, we really don't know what the mechanism
20 of action is.

21 We sort of try to theorize and I think the
22 sponsor I think has talked about how it could have

1 to do with quickly allowing the gut to repopulate
2 and all this stuff. But we honestly, we don't
3 know. But I think you can't rule out that a
4 negative impact is possible.

5 DR. BADEN: Dr. Hilton?

6 DR. HILTON: I believe the way this
7 treatment would be given to patients is as was done
8 in these trials. That is that, once the infection
9 is identified, the treatments would be given. And
10 so conditioning on whether a clinical cure occurred
11 or not doesn't make sense in terms of evaluating
12 the outcome.

13 To me, only the global cure outcome makes
14 sense because the CDI recurrence outcome, those who
15 do not have it include those who did not have a
16 recurrence and those who failed the clinical cure.
17 Sorry. That's hard to explain.

18 DR. BADEN: At this point, it's clarifying
19 questions, and we'll have more time for discussion
20 amongst us.

21 DR. HILTON: Okay. Just one more point,
22 then, regarding the analysis method, following up

1 on Dr. Green's point, is that typically a factorial
2 design, such as P001 used, would analyze -- I
3 forget how the drug is called -- BEZLO, plus or
4 minus ACTO, versus placebo plus or minus ACTO?

5 That wasn't part of the plan, but that would
6 be typical. Then both comparators, the BEZLO and
7 the placebo, would pay the penalty of some patients
8 having ACTO exposure. That's the more traditional
9 way to analyze a factorial design.

10 DR. BADEN: Dr. Daskalakis?

11 DR. DASKALAKIS: My question may not be
12 considered a clarifying question.

13 DR. BADEN: Clarifying, please, Dr.
14 Daskalakis.

15 DR. DASKALAKIS: So I just wanted to ask a
16 theoretical question about the signal in congestive
17 heart failure. So it's a small volume of fluid,
18 250 ccs, so not very much fluid. Is there a
19 biologic theory about why that could be? I mean, I
20 don't think of monoclonal antibodies, unless
21 they're doing something in terms of volume or in
22 terms of osmolarity, creating like a big fluid load

1 that could do something like that. Any idea about
2 what that could be about?

3 DR. HIRUY: So clearly, as you mentioned,
4 the volume is not -- I don't think is the question.
5 And we didn't think it was oncotic pressure either
6 because the CHF's that were observed were, the
7 median was like on day 30. So unless it had some
8 kind of immune-mediated something, because this is
9 a novel therapy and we don't know what the
10 off-target events might be. So other than that, I
11 don't have a clear mechanistic --

12 DR. DASKALAKIS: Could I ask a follow-up?
13 Any sort of in vitro data about cross -- I think
14 you may have mentioned it, but I can't remember,
15 about interaction of this antibody with cardiac
16 tissue?

17 DR. KARTSONIS: Thank you for the clarifying
18 question. So as you know, it is an exogenous
19 target. It's a fully human monoclonal antibody, so
20 the fact that it would have an effect on any tissue
21 is diminished as a result of that.

22 We did do cross reactivity studies in

1 tissues. In fact, we looked at 38 different
2 tissues in both mouse and human, including the
3 aorta and heart in both of those species, and we
4 did not see an effect. We also did preclinical
5 toxicology of repeated dose of administration of
6 bezlotoxumab in mice and also again saw no
7 histopathological effects on the heart, as well as
8 no hemodynamic effects on the heart as well. So
9 from a preclinical standpoint, there is no data to
10 support that finding.

11 As we mentioned earlier this morning, a lot
12 of the events that are occurring, that we're
13 seeing, tend to occur very late, at a point when
14 the exposure of the drug is actually less.
15 Remember, single administration, most of the
16 cardiac events that we did see, both in the 41
17 patients who had serious CHF reported as a serious
18 AE, as well as in the CHF subset at baseline,
19 tended to occur late. And we have no mechanistic
20 explanation for it and we maintain that the data
21 support that there's no negative effect on the
22 heart.

1 DR. BADEN: Any speculation on why?

2 DR. KARTSONIS: Yes, sure, I'd be happy to
3 go into that. I mean, if it's okay, can I have
4 slide 74 up again? 74 was from our base
5 presentation. Yes, please, slide up please.
6 Remember, this is the CHF subset of patients that
7 were included, the 325 patients that were reported.

8 It's important to remember this is not a
9 stratified group, so we're doing an analysis of
10 safety based on a non-stratified group. Not only
11 numerically are there more patients in the
12 bezlotoxumab, but it's not entirely balanced with
13 regard to baseline factors. The proportion of
14 patients who had Charlson Comorbidity Indexes of
15 greater than 5, so that means they have five
16 different conditions that they had at baseline that
17 were considered significant was higher, as well as
18 there were more patients on diuretics, which would
19 be a potential sign that the patients potentially
20 were getting treated for their CHF differently.

21 So if we then go to the next slide, slide
22 75, please, we carefully looked at all of this

1 data. We want to start by looking at the data from
2 week 4 because, if there was going to be an effect,
3 we figure that it would occur at a time when the
4 exposures were the highest.

5 As you can see, the number of patients with
6 any cardiac AE within the first 4 weeks did not
7 differ between the groups. And particularly, the
8 number of patients with a cardiac SAE were
9 numerically higher, but there were no differences
10 in the number of cardiac failures in between
11 bezlotoxumab and placebo. In fact, the lowest rate
12 of cardiac SAEs occurred in the ACTO plus BEZLO
13 groups. So ACTO plus BEZLO is the lowest, placebo
14 is in the middle, and BEZLO is the highest. That
15 doesn't really suggest a potential pattern with
16 regard to those particular findings.

17 Then with regard to the deaths where there
18 is a numerical difference there, I think you saw
19 from the FDA's presentation that most of these
20 deaths were not due to cardiac. We looked at every
21 single one of these deaths and, in fact, the deaths
22 were mostly attributed to neoplasms, renal and

1 urinary events, and infections or other
2 characteristics.

3 Specifically, I think the real way to look
4 at these cases is to delve into each one of them
5 and to look at them. And we've done that. In
6 fact, I don't want to bore the committee. I've
7 already done that to the FDA at our late cycle
8 meeting. But we've looked at each one of these
9 different cases and, in each one of the cases that
10 we see, especially the SAEs, for example, the 11
11 cases that occurred early, each one of them has a
12 reason.

13 There were 3 patients who had cardiac
14 arrest. All of them were 88 years of age or older.
15 There were patients with CHF that were reported.
16 In the 3 patients that led to death due to CHF, 2
17 of them were in the setting of either endocarditis
18 or Enterobacter bacteremia. And the third patient
19 was a patient who had stage 4 CHF, had an AICD in
20 place, developed an arrhythmia, and then went into
21 CHF, and subsequently died.

22 So we believe that it's really a sign of the

1 underlying pathology and the sicknesses of these
2 patients. It's really not attributed to the actual
3 drug itself. We're not disputing the numerical
4 imbalances, but we do believe there's explanations
5 to explain it and we don't believe it's due to
6 BEZLO.

7 DR. BADEN: Thank you. Dr. Goetz?

8 DR. GOETZ: I'm not gainsaying anything the
9 sponsor has said. If I recollect properly the
10 half-life of the drug is approximately 14 days, and
11 thus the timing of adverse events such as drug
12 administration, if there's a cumulative tissue
13 effect, is, I think, perhaps a little bit
14 different.

15 But also, you've talked about histological
16 studies looking at tissue cross reactivity. If I
17 remember right, those are in mice and there are
18 none in any human tissue that I heard. Is that
19 correct?

20 DR. KARTSONIS: They were done in both mice
21 and human tissues.

22 DR. GOETZ: Okay, I missed you saying that.

1 My apologies.

2 DR. KARTSONIS: So I'm sorry about that, but
3 we did look at the in vitro data in mice and human
4 tissues, including both human and mice heart and
5 aorta. And there were no effects there. The
6 half-life of the drug is 19 days. But still,
7 you're going to have your peaks very early and the
8 drug is going to decrease over time.

9 Interestingly, when we did an analysis of
10 all adverse experiences, not just cardiac but all,
11 we didn't really see a time to event. So if
12 there's some late immunological finding, we sure
13 didn't see it because most of the SAEs tended to
14 occur within the first 30 days, in fact, 60 percent
15 of them, and half the deaths occurred in the first
16 4 weeks. So we haven't been able to identify any
17 sort of immunological or autoimmune phenomenon that
18 might explain this, so that's where we are at this
19 point.

20 DR. GOETZ: Thank you. (Off mic).

21 DR. BADEN: Any other clarifying questions
22 for the FDA presentation? Dr. Honegger?

1 DR. HONEGGER: This is again regarding the
2 design and the statistical analysis. I'm sorry,
3 Jonathan Honegger. So my understanding is actually
4 the FDA changed its recommendation from -- there
5 was the design of the first phase 3 trial, and then
6 as the second one was being assessed, the FDA
7 changed its recommendation at that point for what
8 the primary endpoint should be. Is there a reason
9 that they didn't pick it up the first time they
10 prepared the phase 3 trial?

11 DR. DIXON: I was not the reviewer of the
12 protocol for P001, but I was the reviewer for the
13 protocol of P002. And I guess I have different
14 experience regarding trials of this and I picked
15 that up at that time. And I think the focus
16 of -- when the first protocol was being reviewed,
17 they were focusing on other issues of that design
18 rather than how the recurrence rate was defined.

19 DR. HONEGGER: Can I follow that up? So
20 there's a change in the primary endpoint
21 recommendation before the second trial is my
22 understanding. I guess a big question in my mind

1 is, do we need to really look at these A plus B
2 studies or can we just look at the BEZLO alone.
3 And if there's already a change in the primary
4 endpoint, I guess you recognize that there's a
5 problem with clinical cure being a possibility.

6 My question is, for the second one, had the
7 sponsor changed his hypothesis that A could be
8 damaging for clinical cure based upon ACTO plus
9 BEZLO, had impaired clinical cure that was
10 statistically significant in P001 and A alone had
11 impaired clinical cure that was statistically
12 significant in the first trial? Did they change
13 their hypothesis for the second trial suggesting
14 that BEZLO alone might actually be superior than
15 the combination? And if so, can we just take that
16 hypothesis and focus on BEZLO alone?

17 DR. DIXON: The initial program development
18 was based on the combination. And since it wasn't
19 until the results of the trials came out that
20 showed that maybe BEZLO alone was sufficient, I
21 can't ignore the fact that the trials were designed
22 with the combination as the primary focus.

1 DR. BADEN: Dr. Follmann?

2 DR. FOLLMANN: So now I'm curious. Was the
3 discussion about the primary endpoint and changing
4 it made before any data came out or was it made
5 after the results of the first trial came out?

6 DR. DIXON: It was prior to the conduct of
7 the interim analysis for P001. There were no
8 results at the time. Right.

9 DR. FOLLMANN: So no results, and so both of
10 you adopted those positions, you not liking
11 recurrence, then continuing to like recurrence,
12 before you saw any data?

13 DR. BADEN: Dr. Surawicz?

14 DR. SURAWICZ: Chris Surawicz, University of
15 Washington. Can I ask a question about the data
16 that you sent but that wasn't presented about the
17 septic shock and the table 8 in the document that
18 we got? It says, was the negative effect of the
19 ACTO, was that the 33 percent due to deaths?

20 Because in the previous sentence it looks as
21 though sepsis and septic shock were actually lower
22 in the BEZLO and the combo group compared to the

1 placebo group, which made we wonder whether it had
2 some actual benefit in terms of preventing sepsis.
3 It's page 25 of what we were sent on May 23rd.

4 DR. BADEN: Twenty-five of 29 of the FDA
5 document.

6 DR. SURAWICZ: Yes, table 8. Because we
7 heard that the ACTO was discontinued because it
8 wasn't efficacious and actually had it poorer
9 outcomes. Was that sepsis? Was that the reason
10 for the poorer outcomes?

11 DR. HIRUY: Are you talking about ACTO?

12 DR. SURAWICZ: The ACTO-alone segment.

13 DR. HIRUY: I don't actually remember
14 exactly what --

15 DR. SURAWICZ: Okay.

16 DR. HIRUY: -- was the main driving
17 for -- yes.

18 DR. SURAWICZ: Okay. But then the --

19 DR. BADEN: Shall we ask the sponsor to
20 clarify that point?

21 DR. KARTSONIS: So we obviously carefully
22 looked at the data from the interim analysis with

1 regard to ACTO and the potential effect that might
2 have. And if I could actually have slide 684 to
3 start, if that's possible, this is a summary of the
4 data. Actually, if you could, put the slide up,
5 please.

6 This is the summary of how the data looked
7 at the time of the interim analysis, which would
8 have been about 160 patients in each of the 4 arms,
9 40 percent per group. And what you can see here is
10 that there were more serious AEs in the ACTO group
11 as opposed to any of the other groups that you can
12 see there. And particularly, there were more
13 adverse events that led to death in the ACTO group
14 proportionately relative to the other groups.

15 Keep in mind that at this point, the DMC
16 also knew that there was also no difference with
17 regard to efficacy for ACTO alone relative to the
18 combination. In fact, at that point, the p value
19 for difference in terms of recurrence was 0.008.
20 And so taking this data as well as the efficacy
21 data into hand, they were concerned about
22 continuing with the ACTO-alone arm.

1 Now, I will say, we've gone back and looked
2 all of the deaths that occurred in the ACTO-alone
3 group, and we've done that with all the data that
4 we have. In fact, if I could have 673, please,
5 perfect. If you could, please, slide up, please.
6 These are the AEs that were reported that led to
7 death in the ACTO-alone group. You really can see
8 that there's no clustering around any particular
9 event except potentially for sepsis and septic
10 shock where you can see that there were large
11 numbers.

12 Now, I will also point out that, when we
13 look at the total number of deaths, whether it be
14 in the BEZLO group, the ACTO plus BEZLO, placebo
15 group, sepsis is also the leading cause of death in
16 all those groups. So again, we're dealing with an
17 ill, elderly patient population. We've carefully
18 looked at all of the septic and septic shock deaths
19 that occurred in the ACTO group. And if you go to
20 the next slide, 674 - please; slide up, please.

21 Here is a sort of patient by patient
22 description of the different septic shock deaths

1 that occurred in this group. I think there's some
2 interesting patterns that you see, which is that
3 the different types of infections are all over the
4 place. There are gram-positives, there are
5 gram-negatives, there are CDI included in these.

6 The sites of infection also varied from UTI
7 leading to sepsis to other, just plain bacteremia,
8 leg ulcers leading to development of a sepsis. And
9 you can see that the time frame also varied with
10 regard to all of them. Only one of them was
11 reported as C. difficile-related sepsis, which you
12 can see in the third row there.

13 I would also point out the last row, which
14 was the investigator's assessment of death. And
15 you can see that none of these events were
16 considered related by the investigator. So I mean,
17 we still are a little puzzled about what happened
18 with regard to the ACTO-alone arm in the interim
19 analysis, but when you take into consideration that
20 there was no efficacy seen, particularly with the
21 p-value as I mentioned before, and there was this
22 trend toward safety findings, the decision was made

1 obviously to discontinue the ACTO-alone arm.

2 DR. BADEN: So did it cross a stopping rule?

3 DR. KARTSONIS: In terms of efficacy.

4 DR. BADEN: Was the DMC's decision based on
5 futility or based upon a safety signal? And was
6 there a stopping rule that they applied?

7 DR. KARTSONIS: Sure. So the predefined
8 efficacy stopping rule was a p-value of 0.001. Oh,
9 3 zeros. Sorry about that. 0.0001 is called
10 Haybittle-Peto if you ever want to know. It's
11 taken years for me to learn how to say that term.
12 So it did not go below that in that regard, but it
13 was awfully close at 0.008. And keeping in mind
14 also that the safety findings we're seeing, we
15 think the DMC actually made the right decision.

16 In fact, we have now more data that Dalya
17 shared with you in her presentation. Because
18 remember, this was done when 160 patients had
19 reached week 12. There were also additional
20 patients that had been enrolled in the ACTO arm
21 before the interim analysis.

22 We've looked at all of that data, which

1 really was the 242 patients that were shown. And
2 it shows the same trend, both in terms of lack of
3 efficacy as well as the safety finding. So the
4 decision made by the DMC was the correct one, even
5 if it didn't necessarily meet the predefined
6 efficacy rule.

7 DR. BADEN: But it was an integration of
8 both features?

9 DR. KARTSONIS: And that's how the letter
10 was written to -- when the trial was unblinded and
11 we looked at the data from the interim report,
12 those were the two factors that drove the decision
13 by the DMC.

14 DR. BADEN: Thank you. Dr. Surawicz?

15 DR. SURAWICZ: Thank you. Then it looks as
16 though, when you then go back, both the BEZLO and
17 the combo group had less sepsis and septic shock
18 than placebo. So was that statistically
19 significant? It was 23.7 for placebo, 12.5 for
20 BEZLO, and 13.7 for the combo.

21 DR. KARTSONIS: I will call on -- I can't
22 remember that number if it was --

1 DR. SURAWICZ: I was actually asking the --

2 DR. BADEN: It's an FDA question.

3 DR. KARTSONIS: I'm sorry. I apologize.

4 DR. SURAWICZ: It's for them.

5 DR. BADEN: It would be the agency.

6 DR. SURAWICZ: Yes. And again, it's that
7 table 8. It just made me wonder whether it was
8 actually helping or whether it was the fact that
9 the patients had responded to therapy, and they
10 were less sick and therefore less likely to get
11 sick.

12 DR. IARIKOV: Could you please tell what
13 document you're referring to?

14 DR. SURAWICZ: So table 8 of the document
15 that was sent May 23rd.

16 DR. IARIKOV: What table? Sorry.

17 DR. SURAWICZ: It says table 8 summarizes
18 the deaths that occurred in the phase 3 trials.
19 The rates of death were comparable, but the highest
20 proportion of deaths in all study arms was due to
21 sepsis and septic shock.

22 Deaths due to sepsis and septic shock were

1 observed at a higher rate in the placebo arm, 14 of
2 59 or 23.7 percent, as compared to BEZLO, 7 over 56
3 or 12.5 percent, or the combo 7 of 51 and 13.7
4 percent.

5 DR. BADEN: I don't know if --

6 DR. HIRUY: I'm sorry. Can you rephrase the
7 question for us?

8 DR. SURAWICZ: Well, I just wondered if we
9 should pay attention or if it was significant that
10 there was fewer deaths from sepsis and septic shock
11 with the treatment compared to placebo. Or if
12 that's a small difference that we shouldn't pay any
13 attention to.

14 DR. IARIKOV: I would call it -- sorry -- a
15 numerical imbalance. There was no formal
16 statistical analysis associated with these numbers.
17 And this is what's reflected and this is what data
18 showed.

19 DR. SURAWICZ: So not something we should
20 pay attention to?

21 DR. IARIKOV: It's up to advisory committee
22 members.

1 DR. SURAWICZ: It's descriptive not
2 statistically -- it's not significant is what
3 you're saying.

4 DR. IARIKOV: Right. And it was not
5 analyzed formally. There was no hypothesis
6 associated with these numbers. It was observed.

7 DR. SURAWICZ: Thank you.

8 DR. BADEN: Last question from Dr. Goetz,
9 and then we will get to lunch.

10 DR. GOETZ: I'll pass on my question.

11 DR. BADEN: Then we will get to lunch one
12 minute early. So we will break for lunch. We'll
13 reconvene again in this room in one hour at 1:30.
14 Please take any personal belongings you may want
15 with you at this time.

16 Committee members, please remember that
17 there should be no discussion of the meeting during
18 lunch amongst yourselves, with the press, or with
19 any member of the audience. Thank you. See you
20 here at 1:30 prompt.

21 (Whereupon, at 12:29 p.m., a lunch recess
22 was taken.)

A F T E R N O O N S E S S I O N

(1:34 p.m.)

Clarifying Questions (continued)

DR. BADEN: So we should resume the meeting.

And I know some of the panel members have flights to catch, so we will keep things moving and hopefully be done by 4:00. The discussion was ongoing and we had gone through the list of questions, but I think there was one more question that Dr. Weina wanted to raise. And I think he had a graphic to help him ask the question.

STAFF MEMBER: You need to say slide up.

DR. WEINA: Slide up, I guess.

(Laughter).

DR. WEINA: Beam me up, Scotty. All right.

There was a big discussion about whether this -- if the mechanism of action makes sense or doesn't make sense. And if it does make sense, shouldn't it have some influence on the initial infection. And I was just sketching this out and thinking through it.

So my clarifying question becomes, if you

1 look at the upper right -- and a picture is worth a
2 thousand words. And please correct any errors in
3 my thought process here, and maybe this will help
4 us. So if you look at the upper right here, in the
5 initial infection, you have the antibiotic present
6 and you've given the BEZLO. So because of the
7 antibiotics, the bacteria die. The toxin B is
8 bound, but the toxin A is just continuing there and
9 continuing to work.

10 In the case of a recurrence, what is
11 happening is that there is no antibiotics present
12 because basically -- and hopefully the BEZLO is
13 still present because you've shown that it sticks
14 around for quite a long period of time. And as a
15 matter of fact there are some varying -- I mean
16 half-life is very different than when you can still
17 detect it and everything else. But let's say that
18 BEZLO is still around.

19 So the bacteria has to grow, because that's
20 what happens in a recurrence. Otherwise, the toxin
21 B isn't there to be bound, so the idea is that the
22 bacteria is growing, and the toxin B may be bound

1 if the BEZLO is present, and the toxin A just keeps
2 working.

3 Why this becomes important in trying to
4 figure this out is because, if you look at the
5 timeline the microbiota is disrupted, the
6 antibiotic treatment of whatever is there to treat
7 it, C. diff is -- some other infection causes the
8 microbiota to be disrupted, C. diff grows. You
9 have an illness secondary to the toxins A and B.
10 Antibiotic treatment is started for the C. diff.
11 And the BEZLO is added and B is bound.

12 But the bacteria are killed by the
13 antibiotic and the toxin A is still working and
14 somehow 70 percent of them are cured. Of the
15 individuals are cured, 30 percent recur because the
16 bacteria are back, and the toxin B is still bound,
17 and the toxin A is still working. So we're trying
18 to, I think, work out in our head what's wrong with
19 that thinking?

20 DR. KARTSONIS: Your schematic is very
21 intriguing because we -- I'm going to call one of
22 my colleagues, Dr. Therien, back up to show a

1 schematic we've generated, which I think might show
2 similar kind of viewpoints.

3 DR. THERIEN: Yes, I just sketched this down
4 in the last 30 seconds while you were speaking.
5 No, 1128.

6 DR. WEINA: We got to figure out how you
7 guys do it so quick, because it took us the entire
8 break to just figure out how to send it to their
9 computer. Okay?

10 (Laughter.)

11 DR. THERIEN: No, I cheated. I made this a
12 while back. Slide up, please. So this is a
13 representation of I think what you were trying to
14 show. And what this schematic diagram shows
15 essentially is how the healthy -- or the gut
16 microbiota changes over time in the context of a
17 primary and recurrent CDI episode and also how the
18 *C. difficile* burden changes over time in the lumen
19 of the gut.

20 So the blue line represents the gut biota.
21 A blue line at the top of the diagram means that
22 the gut biota is healthy and normal. A blue line

1 at the bottom means that it has been disrupted by
2 antibiotics.

3 So a patient comes into the hospital in this
4 particular representation with a healthy gut biota
5 and is put on antibiotic therapy for whatever
6 reason, another infection or surgery, scheduled for
7 surgery. And that will impact the gut biota and
8 you'll see the blue line start to go down. At some
9 point this patient comes into contact with
10 toxigenic C. difficile spores from the environment.

11 As long as antibiotic therapy is on board,
12 nothing will happen. The biota will continue to be
13 disrupted. The spores will not germinate. But as
14 soon as the antibiotic therapy is completed, the
15 course of antibiotic is completed, then essentially
16 a race begins between Clostridium difficile and the
17 gut biota.

18 The gut biota will start to recover but
19 toxigenic C. difficile spores may germinate,
20 colonize the gut, and start producing toxin which
21 will lead to the clinical manifestations or
22 symptoms of disease, which is what is represented

1 here by the red color that you see. And that
2 patient would then become diagnosed, following a
3 positive stool test, will become diagnosed with an
4 episode of CDI.

5 The patient would then be put on standard of
6 care antibiotics, the gray box at the bottom in the
7 middle there. And for that duration, what you'll
8 see is the C. difficile burden will start to come
9 down, as will the levels of toxins. But also the
10 gut biota, which had begun to recover, now begins
11 to be disrupted again, and you see the blue line
12 going down as well.

13 Essentially, the same story starts again.
14 Once the standard of care antibiotics are
15 completed, the race begins anew and if C. diff wins
16 that race, you get a recurrent episode of CDI, more
17 symptomatology shown by the red color. And that
18 patient again, without any other options, will
19 begin standard of care antibiotics and you get this
20 recurrent cycle that we talk about, where each new
21 episode brings about a higher risk of a further
22 recurrent episode.

1 In this diagram as well, at the very top,
2 you'll see I've highlighted what we consider to be
3 the at risk window. This is essentially the window
4 following successful cure of the initial episode,
5 where the gut microbiota has not yet recovered and
6 where the patient is at risk for CDI recurrence.
7 And you see that the window is limited in time by
8 the start of the recovery of the gut microbiota.

9 So this is what happens in the absence of
10 bezlotoxumab. If we now go to the next slide, you
11 will see what happens in the presence of
12 bezlotoxumab. Slide up. And essentially, what has
13 changed here is that red area for the recurrent CDI
14 has now turned green. And the reason for that is
15 because bezlotoxumab is administered concurrently
16 with standard of care antibiotics. You can see the
17 blue bezlotoxumab at the bottom.

18 We know that bezlotoxumab remains in
19 circulation, because of its long half-life,
20 throughout the at-risk window. And because it's
21 able to bind the toxin that is produced during the
22 recurrent episode of *C. difficile*, it does not

1 impact the growth of *C. difficile*, but it prevents
2 the symptoms of the infection.

3 What you've done here is you've eliminated
4 the need for standard of care antibiotics to treat
5 that recurrent episode. You've eliminated the
6 recurrent cycle and you're now allowing the gut
7 microbiota to revert back to essentially a healthy
8 level, which now provides that long-term protection
9 against further recurrent episodes of CDI.

10 There was a question previously about
11 whether we know whether bezlotoxumab has an impact
12 on the microbiota. We do not have clinical data,
13 but we do have limited preclinical data in the
14 hamster showing that this recovery of the
15 microbiota does happen and that bezlotoxumab does
16 not prevent it from happening.

17 Of course, the whole notion of an at-risk
18 window and of the fact that that at-risk window is
19 associated with disruption of the gut microbiota,
20 and the fact that the at-risk window eventually
21 ends because the microbiota recovers is a
22 well-validated idea in the literature, both in

1 human patients and in animals. And so that part of
2 it has really been demonstrated quite convincingly.

3 Does that clarify things?

4 DR. WEINA: It helps ignoring toxin A.

5 DR. THERIEN: Right, okay. You did talk
6 about toxin A. So the whole question, I now that
7 Dr. Kartsonis replied to, a similar question
8 earlier. Unfortunately, I don't have that much
9 additional data to share.

10 What I can tell you is that there appears to
11 be a dependence on the nature of the host species
12 in terms of what the roles of toxin A and B are in
13 disease. We know that in rodent models, in the
14 hamster and the mouse, you do need both actoxumab
15 and bezlotoxumab. You need to neutralize both
16 toxins to get full efficacy.

17 On the other hand, in the piglet model, that
18 looks a lot like humans, where you only need the
19 bezlotoxumab to get the full efficacy.

20 So there is some sort of a dependence on the
21 host species. I think if you ask some experts,
22 they will tell you that that may have to do with

1 the fact that the receptors for the toxins, the
2 cellular receptors for the toxins on the epithelium
3 are expressed in certain species and not in others,
4 and that that would be the determinant of what the
5 individual roles of toxins A and B are in disease.

6 So I think our data really contributes to
7 the debate that's ongoing in the literature
8 currently about what the roles of toxins A and B
9 are, contributes to that debate arguing that toxin
10 B is the key pathogenic determinant, at least in
11 human recurrent CDI.

12 DR. BADEN: Thank you. Dr. Schaenman?

13 DR. SCHAENMAN: Could you put your slide up
14 again?

15 DR. THERIEN: Certainly.

16 DR. SCHAENMAN: As was said, a picture's
17 worth a thousand words. And I think Dr. Weina and
18 I were really trying to see this from a microbial
19 pathogenesis point of view. But the way you guys
20 are framing the mechanism, what you're really doing
21 is preventing the clinician from retreating the
22 patient by suppressing symptoms.

1 DR. THERIEN: Essentially, that is true,
2 yes. We are essentially preventing the need for
3 that next course of antibiotics.

4 DR. SCHAEENMAN: Right. And just to play
5 devil's advocate for a moment, you could do the
6 same with over-the-counter Imodium arguably, that
7 by suppressing symptoms and that need for
8 retreatment, that's one way to break the cycle.
9 And I've actually heard some C. diff experts
10 recommend that we try to avoid retreating, and
11 maybe that's kind of what the vancomycin taper does
12 in a way. It slowly separates the prescribing
13 physician from the patient.

14 DR. THERIEN: I am happy to deflect that
15 question to our clinician, my clinician colleague.

16 DR. KARTSONIS: Sure. And I can't speak to
17 the potential value of using an Imodium or a
18 Lomotil to do that. But I will tell you, when you
19 look at the totality of the data that we've shown,
20 it's not just preventing loose stools.

21 We've shown that, if you look at the adverse
22 experience, the proportion of patients who actually

1 had serious CDI that was reported as an adverse
2 event was higher in the placebo group versus BEZLO.
3 The severity of the infections, the number of
4 patients who had been treated with a subsequent
5 FMT, the rehospitalization data, the length of stay
6 data, all of that data, we think, does speak to the
7 clinical value of the product that goes beyond just
8 the efficacy endpoint that we mentioned.

9 So I can't directly answer your question
10 because I haven't done that study, but we believe
11 that what we offer with bezlotoxumab as a single
12 infusion over 60 minutes is clearly an advance in a
13 situation where currently there's nothing else. So
14 I'll just stop there and we'll go from there.

15 DR. BADEN: Thank you. Dr. Moore, you have
16 a question?

17 DR. MOORE: Yes, just a quick couple of
18 points. I can't endorse, just as a side note, the
19 use of Imodium in this setting because of the
20 reduction of motility and the increase in time of
21 exposure, but that's a separate issue.

22 DR. BADEN: But it's a different topic.

1 DR. MOORE: Yes, indeed, it's completely
2 different. So moving on, I lost my train of
3 thought. No. The main thing is, the reason that
4 there's a significant recurrence is there continues
5 to be recurrence despite binding of toxin B, is I
6 think the fact that, in the process of doing this
7 particular study, the sponsor sort of stumbled upon
8 or waded into the morass of the unknown about the
9 gut microbiome, as we all have. We've sort of
10 stumbled into it knee deep.

11 The fact of the matter is that it's not just
12 the binding of toxin B which will prevent disease,
13 it's the restoration of gut health. And that's
14 why, although toxin B, binding of toxin B clearly
15 is important, as you see in the data, restoration
16 of gut health with restoration of the microbiome is
17 probably the key factor.

18 Frankly, you're right. Indirectly by
19 reducing or eliminating the possibility of the
20 physician adding on additional antimicrobial
21 treatments, it goes a long way to facilitating
22 that. And what the impact will be with fecal

1 transplant is not clear, but I think that the slide
2 that was shown by the sponsor, and they were sort
3 of wading into the discussion regarding the
4 question to the committee, is that -- I think it's
5 the slide that was shown by the sponsor showing
6 that those that require fecal transplant was
7 significantly less than those who had the placebo
8 really speaks volumes.

9 DR. BADEN: Sorry, I don't think there were
10 statistics on that.

11 DR. MOORE: You're correct, there were not.

12 DR. BADEN: Any other questions or
13 discussion from the committee?

14 DR. SURAWICZ: A quick question. In the
15 people who had no risk factors, was the efficacy
16 different?

17 DR. KARTSONIS: As you know, we only
18 predefined five risk factors in this particular
19 study. And when we look at that subgroup who had
20 no risks -- if you look at the group who had 1 or
21 more risk factors, the difference was 30 percent
22 versus 17 percent, which was over a 50 percent

1 relative-risk reduction, or close to a 50 percent,
2 I should say, relative-risk reduction.

3 In the subgroup that had no risk factors,
4 the difference was 2 percentage points in favor of
5 bezlotoxumab, but the 95 percent confidence
6 intervals do indeed overlap here. But keep in mind
7 that this is the risk factors that we had
8 pre-identified. It doesn't include other risk
9 factors that patients may have, such as renal
10 failure or surgery or concomitant antibiotic use or
11 other things that might also potentially be
12 evaluated.

13 It obviously also doesn't take into
14 consideration that there are some people you may
15 treat even in the setting of no risk factor because
16 they can't have CDI recurrence, they're about to
17 get married, they're about to go on a trip.

18 There's different factors that we're
19 ultimately trying to ensure that the prescribers
20 have access to this medication for all patients in
21 the event of -- you know, based on their judgment
22 if it was the appropriate therapy to give in that

1 setting.

2 **Questions to the Committee and Discussion**

3 DR. BADEN: Thank you. So then if there are
4 no more questions or discussion from committee
5 members, then we'll now proceed with the questions
6 to the committee and panel discussion.

7 I'd like to remind public observers that
8 while this meeting is open for public observation,
9 public attendees may not participate except at the
10 specific request of the panel.

11 We'll be using an electronic voting system
12 for this meeting. Once we begin the vote, the
13 buttons will start flashing and will continue to
14 flash even after you've entered your vote. Please
15 press the button firmly that corresponds to your
16 vote. If you are unsure of your vote, or you wish
17 to change your vote, you may press the
18 corresponding button until the vote is closed.

19 After everyone has completed their vote, the
20 vote will be locked. The vote will then be
21 displayed on the screen. The DFO will read the
22 vote from the screen into the record. Next, we'll

1 go around the room and each individual who voted
2 will state their name and vote into the record.
3 You can also state the reason why you voted as you
4 did if you want to. We'll continue in the same
5 manner until all questions have been answered or
6 discussed.

7 I'd now like to ask Dr. Nambiar to present
8 the question and the charge to the committee.

9 DR. NAMBIAR: Thank you, Dr. Baden. Today's
10 meeting we've discussed the benefits and risks of
11 bezlotoxumab for the prevention of C. difficile
12 recurrence. As we've stated earlier, the applicant
13 is seeing approval of bezlotoxumab for the
14 prevention of recurrence of Clostridium difficile
15 infection in patients older than 18 years of age.

16 You've heard presentations from the FDA and
17 the applicant regarding the safety and efficacy of
18 this product for the proposed indication and heard
19 the comments submitted to the open public hearing.
20 Based on the information provided to you in the
21 briefing documents, the presentations, and
22 discussions today, we seek your input on one voting

1 question.

2 From an efficacy standpoint, as you've
3 heard, there are differences in assessment between
4 the applicant and the agency.

5 You've heard a lot of discussion about the
6 considerations for appropriate endpoint and
7 analysis populations, and the observed differences
8 in cure rates for the initial CDI episode between
9 the antibody arms and the placebo arm, and the
10 potential impact of these findings on the efficacy
11 assessment of bezlotoxumab in the prevention of CDI
12 recurrence.

13 We would appreciate receiving your advice on
14 these issues and any other aspects of the efficacy
15 assessment that you consider important.

16 From a safety standpoint, while there are no
17 major safety concerns identified so far, you've
18 heard discussions regarding the observed imbalance
19 in serious adverse reactions in a subgroup of
20 patients with congestive heart failure. So as
21 always, in addition to your votes, we greatly value
22 and benefit from the rationale you provide to

1 support your decision and any recommendations that
2 you might have regarding this application.

3 So the single question we have for the
4 committee is, has the applicant provided
5 substantial evidence of the safety and
6 effectiveness of bezlotoxumab for the prevention of
7 C. difficile infection recurrence in patients aged
8 18 years and older?

9 If yes, please discuss your rationale and
10 provide any recommendations concerning labeling.

11 If no, please discuss your rationale and what
12 additional studies or analyses are needed. Thank
13 you.

14 DR. BADEN: Any clarifying questions from
15 the committee about the question to us that we can
16 ask the agency to clarify for us?

17 (No response).

18 DR. BADEN: Seeing none, then, if there are
19 no questions or comments regarding the wording of
20 the question, we'll now open the question to
21 discussion. I realize we've had hours of
22 discussion. And I see --

1 UNIDENTIFIED PANEL MEMBER: (Inaudible - off
2 mic) -- discussion amongst ourselves.

3 DR. BADEN: Just amongst the committee about
4 the question. Dr. Follmann?

5 DR. FOLLMANN: Well, in the space of two
6 minutes, I've gone from abstain to -- well I won't
7 tell you what I'm going to do actually. I suppose
8 that's not right. But anyway, so what I'm looking
9 at is, has the applicant provided substantial
10 evidence of the safety and effectiveness?

11 I was interested in an analysis where we'd
12 start at, say, day 28, look at whether or not you
13 had 3 loose stools or not in a day, count that as a
14 failure, count deaths as a failure additionally as
15 a sensitivity analysis. To me, that's a very
16 important analysis and it hasn't been presented
17 today. So I would mention that.

18 The other thing has to do I guess with the
19 recurrence. That word to me means, and I think it
20 would to most people, gee I'm cured of whatever,
21 now I'm at risk for it coming back. And if it does
22 come back, then I've recurred. But in fact that's

1 really not the design of this study. And so to me,
2 to say the word recurrence would be a study like
3 you suggested where you basically randomize those
4 who are cured, maybe start giving the antibody at
5 day 13 or so. So anyway, those are the points that
6 I'm thinking about.

7 DR. BADEN: Your point is well taken that we
8 have to weigh the data that are before us, not the
9 data we hope to have.

10 DR. FOLLMANN: Or what we think it might
11 look like.

12 DR. BADEN: Dr. Weina?

13 DR. WEINA: Pete Weina, Walter Reed. Just
14 one question for the agency. Did you specifically
15 mean to say effectiveness versus efficacy, or is
16 that not a distinction in your mind?

17 DR. COX: It's safety and efficacy, but it's
18 oftentimes a question of effectiveness. So yes,
19 we're talking about efficacy. And just to clarify
20 what we're talking about, oftentimes people refer
21 to effectiveness as how a drug works in the real
22 world. And I'm assuming that's what you mean when

1 you say effectiveness.

2 DR. WEINA: That's exactly what I mean.

3 DR. COX: Yes. We're talking more safety
4 and efficacy, the traditional use of the words as
5 we use it. Sometimes we use effectiveness almost
6 synonymously with efficacy.

7 DR. BADEN: Dr. Andrews?

8 DR. ANDREWS: Ellen Andrews from the
9 Connecticut Health Policy Project. I guess, to
10 your point about effectiveness, when I think of
11 effectiveness for patients, it's getting well and
12 being able to go to that wedding, or whatever. And
13 the adverse events, even though they were meant to
14 talk about safety, I would have expected to see
15 some reduction in not just deaths, but also
16 diarrhea, and nausea, and some of those other kinds
17 of problems.

18 I didn't see that and I know that that
19 wasn't a study done to look for that kind of
20 effectiveness, but that's what I see there and it's
21 troubling.

22 DR. BADEN: Dr. Honegger?

1 DR. HONEGGER: Since we're just talking
2 amongst ourselves, I think they did show a
3 reduction in diarrhea because they talked about
4 all-cause diarrhea and not just C. diff specific
5 diarrhea.

6 DR. BADEN: Dr. Green?

7 DR. GREEN: I'm a little troubled by the
8 full question which includes looking at prevention
9 in patients aged 18 or older. I didn't actually
10 hear any data or discussion about patients 18, or
11 19, or 25, or 30.

12 I'm a pediatrician and I suspect that, if
13 this gets FDA approval, our clinicians will use it
14 before it's studied and FDA approved in kids. We
15 often have to do that because studies in kids lag
16 far behind.

17 But I don't really know how well it works in
18 this age group. I don't really know how well it
19 works in individuals who are not so severely
20 affected or do not have such risk factors. It does
21 seem that there's a population that gets benefit
22 from it. And I have -- as someone who longs to see

1 more anti-infectious agents available, but also
2 just --

3 DR. BADEN: Dr. Green, I think the question
4 now is understanding the question and discussion of
5 the evidence, not our rationale. We take a vote
6 and, after we vote, we provide rationale and advice
7 to the agency. So this is more, do we understand
8 the question, do we understand the data?

9 DR. GREEN: Okay.

10 DR. BADEN: Hence the effectiveness versus
11 efficacy to make sure, and then we will have a
12 chance after we vote to explain pros and cons of
13 our opinions. So other clarifying questions or
14 discussion that will help inform understanding the
15 data and the question?

16 (No response).

17 DR. BADEN: Okay. If there's no further
18 discussion on this question, we will now begin the
19 voting process. Please press the button on your
20 microphone that corresponds to your vote. You will
21 have approximately 20 seconds to vote. Please
22 press the button firmly. After you have made your

1 selection, the light may continue to flash. If you
2 are unsure of your vote or wish to change your
3 vote, please press the corresponding button again
4 before the vote is closed.

5 So I guess the voting may now begin. So
6 please all make sure you vote. And we now have the
7 sign, so the voting is now complete.

8 (Vote taken.)

9 DR. TESH: For the record, the voting result
10 is 10 yes, 5 no, and 1 abstention.

11 DR. BADEN: Now that the voting is complete,
12 we will go around the table and have everyone who
13 voted state their name, vote, and, if you want to,
14 you can state the reason why you voted as you did
15 into the record. We'll start with Dr. Surawicz in
16 the right.

17 DR. SURAWICZ: Thank you. I voted yes. I
18 think these were well done studies that were very
19 detailed. They provided us with a tremendous
20 amount of data. We know the severity of recurrent
21 C. diff and its impact. I believe that the sponsor
22 showed that it was efficacious and overall very

1 safe. I would hope that it would be used for
2 high-risk patients and not for everyone. And I
3 would hope that the safety data would continue to
4 be collected after its use if it is approved.

5 DR. BADEN: Dr. Goetz?

6 DR. GOETZ: Yes, I'm Dr. Goetz from the VA
7 and David Geffen School. I also affirm my vote as
8 yes. And I was, as Dr. Surawicz was, impressed by
9 the quality of the study, the depth of the analyses
10 performed by the sponsor, as well as by the FDA
11 whose analyses I very greatly appreciate.

12 Thinking about this as a whole, the word
13 substantial is an important word to me, always
14 means not without a shadow of a doubt, but really
15 the overwhelming body of data supported this. I
16 voted yes, although I have some concerns about the
17 word recurrence because I think that what's more
18 important to the clinician, and as well as to the
19 patient, is what might best be termed as sustained
20 clinical response.

21 Cure is a hard word to use because relapses
22 occur in funny ways. But sustained clinical

1 response is a better phrase, in my view,
2 recognizing that the sustained clinical response is
3 likely driven by a lower recurrence rate. But
4 because of the nature of the study design, it makes
5 it a little bit more challenging just to look at it
6 in terms of recurrence.

7 As is Dr. Surawicz, I'm concerned about
8 identification of populations who will most benefit
9 because of the value equation of the medication
10 more than the safety and risk profile of the
11 medication.

12 If I heard the sponsor properly a few
13 moments ago, in the approximately 25 percent of
14 patients who had zero of the -- none of the five
15 identified risk factors. The delta between the
16 2 arms, the BEZLO arm, placebo arm, is 2 percent
17 and the confidence interval is less clearly
18 crossing zero.

19 So I think there is a value judgment that
20 will need to be made. And while I would not
21 necessarily restrict the package label to people
22 who have a risk factor, I think it's an item that

1 merits consideration here.

2 I applaud the sponsor for the data they are
3 collecting to allow them to evaluate some of the
4 nuances and looking at the microbiome is an
5 important factor here to substantiate some of the
6 data. I think there are questions that need to be
7 looked at in sub-analyses regarding timing of the
8 therapy. Repeat dosing wasn't addressed. It's an
9 important issue that will come up clinically most
10 certainly. I think those cover my primary issues
11 here. Thank you.

12 DR. BADEN: Dr. Hilton?

13 DR. HILTON: I'm Joan Hilton, a
14 biostatistician from UCSF. I voted yes in spite of
15 a number of study design weaknesses. For example,
16 it would have been nice to randomize after the
17 initial infection was resolved to see if that would
18 delay recurrence.

19 I agree with Dr. Goetz's comment that
20 sustained response would be a nice definition to
21 pursue. I was also concerned about the roughly
22 60 percent of subjects with at least one treatment-

1 emergent adverse event. But when I looked across
2 the types of individual events, the most common was
3 less than 7 percent. So I think that these are
4 very sick patients, and they're having a lot of
5 symptoms in the setting that they're in, and
6 probably those cannot be avoided and will resolve
7 relatively quickly.

8 So I think, given the environment of strong
9 medical need for treatments for C. difficile, in
10 spite of the weaknesses, I decided to vote in favor
11 of this.

12 DR. BADEN: Dr. Moore?

13 DR. MOORE: I voted yes, of course, as you
14 see in the table. But I won't reiterate most of
15 the -- most of my concerns have been previously
16 stated.

17 The only thing I would say, it's a difficult
18 question to answer properly because the safety and
19 effectiveness were lumped into the same question
20 and not separated and that raised its own issues.
21 So the only thing I would say regarding safety is,
22 this drug I think might have to -- you might have

1 to stipulate, the FDA might want to stipulate that
2 if the drug is going -- that it should be used with
3 caution in patients who have heart problems. That
4 said, it's about the only thing I would recommend.
5 Beyond that, I didn't see any overriding
6 significant safety concerns.

7 With regard to effectiveness, I think the
8 data were -- no matter how you slice it, I mean, I
9 really want to thank the FDA for their very
10 thorough dissection and interpretation of the data,
11 as well as the sponsor for the heavy lifting that
12 was done.

13 It's a difficult spot to be in as an
14 advisory committee member to walk into a
15 disagreement between the sponsor and the FDA, but I
16 think it's an amicable disagreement. And I think,
17 largely, the difficulties were resolved to my
18 satisfaction, I guess, is what I'm trying to say
19 for the purpose of this voting.

20 DR. BADEN: Dr. Gea-Banacloche?

21 DR. GEA-BANACLOCHE: I voted yes. I think
22 that the description, the analyses of the FDA, it

1 says everything really. I think that they were
2 right saying that the most important endpoint
3 should have been the global cure and not the
4 recurrence. And I think it's unfortunate how
5 things develop. But I think that the FDA is also
6 right when they say that it does seem like there is
7 a decrease in recurrence of C. difficile when you
8 use this drug.

9 I think it's a big concern that by approving
10 this drug we're going probably to multiply by a
11 factor of I don't know how many hundreds the cost
12 of treatment of C. difficile and probably the cost
13 of preventing 1 recurrence is going to be I don't
14 know how much. So that's a big concern in terms of
15 how the FDA is going to phrase the approval and in
16 which patients these drugs could be used.

17 I think that the immediate tendency of start
18 treatment and give your monoclonal antibody is
19 going to exist there. But I cannot see anything in
20 these data that says these drugs should not be made
21 available. I think that there should be a place
22 for it and that's the reason I voted yes.

1 DR. BADEN: Ms. Thomas?

2 MS. THOMAS: Jeanine Thomas, MRSA Survivors
3 Network. In my opinion, this therapy is not
4 significantly better than the placebo. Sponsor has
5 not proven efficacy and the side effects and
6 mortality rates are too high. As a C. diff
7 survivor myself, I am very concerned about the gut
8 microbiome being compromised. I believe further
9 studies would not improve the effectiveness of this
10 therapy. We need superior therapies.

11 DR. BADEN: Dr. Honegger?

12 DR. HONEGGER: Jonathan Honegger. I voted
13 yes. I recognize the concerns and appreciate the
14 concerns of the FDA about the endpoint. These were
15 well-done studies and large studies in appropriate
16 populations. And I was driven particularly just by
17 the urgent need for targeted therapy for C. diff.

18 I also hope these are used primarily in
19 high-risk. I hope that follow-up studies are done
20 to help further clarify its role in people who are
21 not high-risk people, safety effects in CHF and
22 other cardiac disease, repeat dosing, and then of

1 course in children looking at PK and eventually
2 efficacy. I don't know -- I'll just stop at that
3 point. Thank you.

4 DR. BADEN: Dr. Schaenman?

5 DR. SCHAENMAN: Joanna Schaenman, UCLA. I
6 also voted yes. Although I still have some
7 questions about what the mechanism truly is, I
8 think there's no question that it is a novel
9 mechanism. And as I think was mentioned earlier,
10 we haven't had any new drugs in our armamentarium
11 for C. diff for some time, so I think there's
12 definitely room for something like this, which is
13 so novel.

14 I also appreciated the sort of the
15 statistical dialogue between the sponsor and the
16 FDA. I thought it was very elucidating. And I
17 want to echo some of the comments mentioned
18 previously that if approval is given, attention
19 should be given to the wording in terms of what
20 this drug is actually doing in terms of global
21 cure. And I would also encourage FDA to include
22 some of Dr. Follmann's requested analyses in the

1 package labeling if it does come to that point.

2 I also want to echo what's been said
3 previously regarding targeted therapy. As Dr.
4 Goetz mentioned, the impact seemed most minor in
5 those least at risk patients. And because although
6 the study concerns didn't reach the burden, to me,
7 that seemed to prevent approval.

8 Certainly, there was some safety signal in
9 the CHF patients, and so because we're always
10 balancing risk-benefit, I think the role for this
11 drug would be in high-risk patients, in patients at
12 risk of recurrence. In those patients, the risk
13 for potential heart effects would potentially
14 outweigh -- the benefit would outweigh the risk.
15 And so again, targeted therapy I think would be the
16 best utilization.

17 I would also encourage the sponsor to
18 continue looking at the time of use as it relates
19 to standard of therapy because maybe there is the
20 right niche between balancing all these different
21 things, restoration of microbiome, active
22 antibacterial therapy, and addition of a biologic

1 where we could orchestrate best the use of these
2 different therapies.

3 DR. BADEN: Dr. Weina?

4 DR. WEINA: I voted yes. Has the applicant
5 provided substantial, yes but not conclusive
6 evidence of safety and efficacy, especially given
7 the 2011 data and the unmet medical need, we're
8 probably preventing possibly up to 8000 cases a
9 year, and possibly up to 3000 deaths a year. So
10 given the unmet medical need, I think that there's
11 a reason to -- that there's substantial but not
12 conclusive.

13 I do have concerns about that maybe there
14 should be a warning, not necessarily a black box
15 warning, but some sort of warning on CHF, maybe a
16 phase 4 trial suggesting looking at the isolates.
17 And actually focusing on -- I mean, given the
18 mechanism of action that's been discussed, you
19 would expect something better than a 10 percent
20 improvement. You would expect something much more
21 substantial. So maybe there are isolates that it
22 works better for and not other isolates, and that's

1 why we're seeing the difference. And maybe get a
2 closer look at that.

3 I would also encourage the agency to really
4 look more closely at the issue of cross-reactivity
5 even though BEZLO doesn't really have "an
6 endogenous target" that's been identified because
7 toxin B is the target. It doesn't really rule out
8 cross reactivity. And really looking at the
9 tissues that are used and potentially looking for
10 other potential reasons why you may be seeing some
11 of the concerning, quote/unquote, "safety signals"
12 could be found by looking at that for
13 cross-reactivity.

14 DR. BADEN: Dr. Gripshover?

15 DR. GRIPSHOVER: Hi. I'm Barb Gripshover,
16 and I voted yes also. And I really appreciated the
17 FDA's concerns of the primary endpoint of the
18 study. I agree that it seemed like not the best
19 choice, but I think the sponsor did a really good
20 job of looking at other data. And I think I might
21 have been most moved by looking at the cure rate
22 when you expanded your cure rate and showed that,

1 at all time points, it was making a difference.

2 So I think that it does seem that the drug
3 is effective for preventing recurrence for a
4 significant number of people, so that's why I voted
5 yes. I do think that we want to go with high-risk
6 populations because I think that the benefit may
7 not be there for people that don't. And that's it.

8 DR. BADEN: Lindsey Baden. I voted no, but
9 I suspect my views are not that divergent from
10 others. It's just how to weigh the evidence. I
11 think that the question is substantial evidence,
12 not preponderance of evidence, and not evidence
13 that we're not able to evaluate but can be shown as
14 supportive. I find that potentially tricky.

15 This is not a rare disease. Five hundred
16 thousand cases a year in the U.S. alone. And we
17 have 800 patients in total treated with the therapy
18 of interest. And based on that, we make
19 conclusions of safety, and based on that we're
20 making conclusions of efficacy that getting to
21 third base is substantial, getting to third base or
22 getting to home base. Not being a sports person,

1 it's dangerous to make analogies.

2 I think there is a preponderance of
3 evidence, but the issue of substantial evidence, to
4 me, is a very high bar for a first-in-class, novel
5 therapy for which we have no experience and which
6 we have a lot of hope, and desire, and need, and I
7 want my patients to have this. But the data that
8 we have to date, in my view, are conflicting.

9 I think both the sponsor and the FDA did a
10 fabulous job at presenting a lot of data from many
11 different sides. Many aspects of the data were
12 incomplete and we wanted more, but in part there is
13 time limitations as to how much we could discuss.
14 But I'm leery of data that I want to see tomorrow
15 versus the data we have today that we're able to
16 scrutinize and evaluate. And I think some of the
17 discussion alluded to data that will be generated
18 from this dataset that will be informative. When
19 we have those data, then they can be evaluated and
20 incorporated.

21 Then there is the question of how to look at
22 the global cure. And if one looks, the 3 out of

1 the 4 groups that received the antibody did worse
2 in clinical cure. And 1 group did better. And
3 then with recurrence, I think there was clear
4 signal of benefit. That's a complicated analysis
5 to interpret.

6 Then redefining the goalpost of what
7 clinical cure is and being able to evaluate those
8 data only from a few slides presented today makes
9 it very hard to have confidence in understanding
10 those data. So I'm torn by the data that we have
11 versus the data that I want and that this is not a
12 rare disease.

13 So the ability to do studies should not be
14 difficult in larger populations, so we have the
15 data we need to make a decision about substantial
16 efficacy in the right population versus the hope
17 and implication that it should work the way we
18 think it should. And I'm leery of it should versus
19 we have the data in humans that demonstrate the
20 activity as we expect.

21 So I think there is a cloud in my mind over
22 the efficacy that I think the sponsor has an

1 analysis that makes sense. To me, this seems like
2 they jumped from a phase 2 to two phase 3s. And
3 really, the two phase 3s, in my mind, are the 2bs
4 that design the endpoints that should be the
5 endpoints that get confirmed because we're now
6 changing the primary endpoints of the study.

7 I don't think that it's wrong. I think we
8 learned. We learned a lot from this study about
9 the biology of C. diff that we didn't expect. But
10 I'm uncomfortable declaring conclusions of
11 substantial efficacy and safety based upon data
12 from 800 with analyses that are fluid for very good
13 reason, but are still fluid.

14 So I think the discrepancies in the data on
15 the clinical cure, the issues in the change of
16 endpoint, additional analyses that are not
17 available, the additional studies that many of us
18 have mentioned, the safety signal with CHF, all in
19 the setting of 800 total treated for a first-in-
20 class do not reach the bar for me of substantial
21 efficacy.

22 It's a preponderance. It is a very

1 intriguing and encouraging intervention, but the
2 level of proof is not there yet in my view.

3 Dr. Green?

4 DR. GREEN: Michael Green, University of
5 Pittsburgh, Children's Hospital, Pittsburgh. I
6 voted yes. First off, I want to thank both the
7 sponsor and also the FDA for their analysis, their
8 presentation, their ability to respond to our
9 questions. I want to thank my fellow committee
10 members because I think your questions really
11 helped me to further understand what we were seeing
12 and to try to put it into context.

13 I voted yes as a pediatrician when this
14 study was really done primarily in a geriatric
15 population, and my yes is probably not an
16 unconditional yes, but we didn't get to limit our
17 recommendation other than to say how we might like
18 to see it used or what might be on the product
19 recommendation.

20 I think there is evidence that there is a
21 role in a particular population. I think that the
22 fact that those with risk factors and those with

1 more important or severe disease seem to have the
2 greatest benefit. And they're also probably the
3 ones that are at greatest risk from this disease,
4 although I don't take care of those individuals on
5 a day-to-day basis, suggest that there is a role
6 for them.

7 I would hope that this product would not be
8 used in individuals who did not really have those
9 risk factors or have severe disease. And in fact,
10 the company's own presentation suggested that they
11 did not show a statistical benefit in that group.
12 I have no idea of how well it works in an
13 18-year-old, even though we're talking about an
14 indication down to 18, in particular an 18-year-old
15 without risk factors.

16 I know, although I wasn't allowed to say
17 this before -- I can say it now -- that my
18 intensivist in my ICU at the Children's Hospital of
19 Pittsburgh will be thinking that they should use
20 this because more is better. And I fear that and I
21 do fear the cost.

22 Yet, I do really believe that there is a

1 population for whom this should be targeted and is
2 likely to show some benefit, in part because there
3 is not a lot of good alternatives. I urge and beg
4 the sponsor to do additional studies, particularly
5 in the pediatric population, and to take what we've
6 learned by our input, your input, the FDA's input,
7 and try to perfect those studies, and to do
8 additional phase 4 studies.

9 I also would echo the previous comments
10 about caution in those with underlying heart
11 disease since we don't really understand exactly
12 what that signal is representing or why it's
13 occurring. Thank you very much.

14 DR. BADEN: Dr. Daskalakis?

15 DR. DASKALAKIS: Demetre Daskalakis, New
16 York City Department of Health. I wanted to start
17 off again by echoing the thanks that you've heard,
18 both to the agency and the sponsor for really great
19 presentations and very detailed analyses.

20 I will the reveal that I have trained under
21 Dr. Baden, so I'm going to sound just like Dr.
22 Baden right now, which is that we have had a very

1 limited experience with this drug purely in these
2 studies. There are about less than 800 experiences
3 of people on this drug alone, and that makes me
4 very concerned from the perspective of this data
5 being convincing.

6 I think that it both confounds the safety
7 signal and also potentially confounds the efficacy
8 signal. I am concerned that we have a mixed signal
9 on the effect of this drug on treatment.

10 So we talk about recurrence being an issue
11 and what I fear is that, as this drug rolls out,
12 more being better than less, that more and more
13 people who potentially would just get treated and
14 be fine will be exposed to this agent. And if
15 there is an adverse effect on treatment, that could
16 be a significant impact both on the healthcare
17 system and the health of individuals.

18 So I think it's really critical, if this
19 does sort of proceed, that there are more phase 4
20 studies done to really see what's happening with
21 the drug from the perspective of it looked in
22 isolation rather than in the context of other

1 agents.

2 From the perspective of safety, the CHF and
3 death signal, I think, is actually significant.
4 And the reason that I say that is because of this
5 very good conversation we've had in the context of
6 this committee that people are saying, "I hope this
7 is used for people with risk factors." Well, that
8 also means that you're going to be using it in
9 people who have CHF. So if you look at the
10 definition of CHF, it's really permissive. Pretty
11 much if you have a little bit of failure, you're
12 going to qualify as a CHF patient in this study.

13 So I am concerned that we don't really have
14 a sense of the safety. We haven't had enough
15 experience with 800 people on the drug to be able
16 to proceed in this way. Which is one of the
17 reasons that I voted no.

18 I think, otherwise, a lot of what I've said
19 has been said before. And like I think that Dr.
20 Baden said, it's in the eye of the beholder. I
21 think that much of my thoughts are similar to the
22 people who said yes, but I am concerned that we

1 need more experience.

2 DR. BADEN: Thank you. Dr. Andrews?

3 DR. ANDREWS: Ellen Andrews for the
4 Connecticut Health Policy Project. I also agree,
5 I'm probably in agreement with everybody around the
6 table, but I voted no. I think it has enormous
7 potential.

8 I especially want to thank the sponsor, for
9 I think this might be the first time I've ever
10 voted no on anything, because we need more tools in
11 the toolbox. We absolutely do, so I'm very happy
12 that you're working on this.

13 But this is given to very fragile people,
14 which I get is why it makes looking at the safety
15 data that's concerning me so much problematic. But
16 it also means that you're giving this to fragile
17 people. And if there's any chance that it
18 interferes with a cure, that's a real concern.

19 I think that really needs to be sorted out
20 before we give it to people who are fragile and
21 looking at a pretty serious infection.

22 Why we can't give -- I've still not heard a

1 great explanation for why we can't give this drug
2 after the cure at day 14. So I'm worried about
3 that. I'm worried about changing the definition of
4 cure. I am worried about people with heart
5 failure. I think, if it is approved, it should be
6 limited to people, especially to people it worked
7 the best for, people who have had infections in the
8 past. They are going to be at risk and it's more
9 likely to work for them. I just don't think it's
10 quite ready yet, but I think it has enormous
11 potential. Thank you.

12 DR. BADEN: Dr. Corbett?

13 DR. CORBETT: So I abstained from voting,
14 which like Ellen I've been to many of these
15 meetings, never abstained, and I don't think I've
16 ever voted no. And I would say I also agree with
17 pretty much what everyone is saying, and that was
18 really my difficulty in truly at this very moment
19 saying yes or no, because I think all these things
20 are true.

21 Still, my biggest challenge is really
22 not -- I know we've approved drugs before; we don't

1 know exactly the mechanism. I can name several of
2 those. But I'm still really struggling, especially
3 that we're trying to really focus in on how drugs
4 are best used for individuals that I just feel
5 uncomfortable that we don't have more information
6 on that.

7 I am truly grateful for Merck for looking at
8 this type of therapy in individuals, especially a
9 non-antimicrobial approach for someone with an
10 infection. This is huge. It's wonderful. So I
11 commend you on that, also for the FDA for being
12 very mindful of the data and how the data was
13 analyzed and how it was looked at.

14 So I do think eventually this will be a
15 very, very promising drug. I think it is already.
16 I just don't feel currently that I felt very
17 strongly that it should be approved immediately.

18 DR. BADEN: Thank you. Dr. Follmann?

19 DR. FOLLMANN: I'm Dean Follmann. I voted
20 no. I think I agree with a lot of what's been said
21 so far. And I'd like to -- I thought the sponsor
22 did a great job, and the FDA did a great job, and

1 the committee had a lot of great discussion also.

2 I was interested in a particular kind of
3 analysis that I think will show benefit for both
4 studies but it wasn't done, and so for that reason
5 I voted no largely. I think if the analysis for
6 the late diarrheal success endpoint I had talked
7 about showed success, I probably would have voted
8 yes.

9 The chair talked about some trepidation
10 about changing endpoints going on in a study and
11 that's something I agree with should be done with
12 caution. But in my mind, in this setting, the
13 primary endpoint, I thought, was deeply flawed as
14 the FDA pointed out, where non-cures were called
15 successes.

16 So that leaves open a new world where I
17 think we have more license to use our thinking
18 about what kind of endpoints we would view as
19 convincing and we're not beholden to the thinking
20 of other people. And so that's why I feel I have a
21 little more license here to go with that endpoint.

22 So anyway, I did vote no. I probably would

1 have voted yes if I'd seen that analysis that I
2 liked. As I mentioned earlier, I'm wary of the
3 word recurrence because I think it means you've
4 done a different study than you have done. I would
5 prefer something that's more neutral that doesn't
6 suggest that you're cured when you start this
7 therapy because you're not.

8 The only other thing I would mention is
9 there's been talk about risk and how the treatment
10 might vary with baseline risk and, including the
11 subgroup that had no risk factors at baseline, I
12 imagine that's a pretty small group.

13 So if we're just seeing whether it's
14 beneficial, if there's a benefit in that group, the
15 study wasn't powered for that or anything, I think
16 the proper thing to do would be to look at whether
17 the treatment effect in that group differs from the
18 other group, do formally a statistical test of
19 interaction.

20 The statisticians will know what I'm talking
21 about, but be prudent about carving out rare
22 subgroups and saying, oh, it doesn't work here.

1 And that's all I have to say.

2 DR. BADEN: Thank you. Before we adjourn,
3 are there any last comments from the FDA?

4 DR. NAMBIAR: Thank you, Dr. Baden. I just
5 wanted to take this opportunity to extend my thanks
6 and sincere appreciation to the committee members
7 for all the advice provided and the discussions
8 were very helpful. They're certainly very
9 beneficial to us as we continue to evaluate the
10 application further.

11 I also want to extend our thanks to the
12 applicant for their presentations and all the hard
13 work with this application. And I also want to
14 thank the speaker at the open public hearing for
15 their comment. Wish you all safe travels. Thank
16 you again.

17 **Adjournment**

18 DR. BADEN: We will now adjourn the meeting.
19 Panel members, please take all your personal
20 belongings with you as the room is cleaned. All
21 material left on the table will be disposed of.
22 Please remember to drop off your name badge at

1 registration so they may be recycled. Thank you
2 all for your attendance and participation.

3 (Whereupon, at 2:30 p.m., the meeting was
4 adjourned.)
